ABSTRACT

In this work, we present constraints on different shapes of primordial non-Gaussianity using the Wilkinson Microwave Anisotropy Probe (WMAP) seven-year data and the spherical Mexican hat wavelet \( f_{nl} \) estimator including the linear term correction. In particular, we focus on the local, equilateral and orthogonal shapes. We first analyse the main statistical properties of the wavelet estimator and show the conditions to reach optimality. We include the linear term correction in our estimators and compare the estimates with the values already published using only the cubic term. The estimators are tested with realistic WMAP simulations with anisotropic noise and the WMAP KQ75 sky cut. The inclusion of the linear term correction shows a negligible improvement (\( \lesssim 1 \) per cent) in the error bar for any of the shapes considered. The results of this analysis show that, in the particular case of the wavelet estimator, the optimality for WMAP anisotropy levels is basically achieved with the mean subtraction, and in practical terms there is no need of including a linear term once the mean has been subtracted. Our best estimates are now \( \hat{f}_{nl}^{(loc)} = 39.0 \pm 21.4 \), \( \hat{f}_{nl}^{(eq)} = -62.8 \pm 154.0 \) and \( \hat{f}_{nl}^{(ort)} = -159.8 \pm 115.1 \). We have also computed the expected linear term correction for simulated Planck maps with anisotropic noise at 143 GHz following the Planck Sky Model and including a mask. The improvement achieved in this case for the local \( f_{nl} \) error bar is also negligible (0.4 per cent).

Key words: methods: data analysis – cosmic background radiation – cosmology: observations.

1 INTRODUCTION

In the recent years, the spherical Mexican hat wavelet (SMHW; Martínez-González et al. 2002) has been used to construct a new type of estimator for the primordial non-Gaussianity in the cosmic microwave background (CMB) characterized by the non-linear coupling parameter \( f_{nl} \) (Curto et al. 2009a, 2011b; Curto, Martínez-González & Barreiro 2009b, 2010, 2011a). One of the particularities of the wavelet estimator as it has been traditionally presented in the literature compared with direct bispectrum-based estimators (Komatsu & Spergel 2001; Komatsu et al. 2002, 2003, 2005, 2009, 2011; Babich, Creminelli & Zaldarriaga 2004; Babich 2005; Creminelli et al. 2006, 2011; Creminelli, Senatore & Zaldarriaga 2007; Spergel et al. 2007; Yadav & Wandelt 2008; Elsner & Wandelt 2009; Smith, Senatore & Zaldarriaga 2009; Liguori et al. 2010; Senatore, Smith & Zaldarriaga 2010; Smidt et al. 2010; Fergusson, Liguori & Shellard 2010a,b; Fergusson & Shellard 2011) is the absence of a linear term. In the bispectrum-based estimators, the linear term plays a key role to achieve optimality in the cases where the rotational invariance of the CMB is broken because of different instrumental complexities such as anisotropic noise or partial sky coverage (see for example Creminelli et al. 2006, 2007; Yadav & Wandelt 2010; Fergusson & Shellard 2011). The computational difficulties related to the inversion of the covariance matrix present in the bispectrum estimator, especially in future data sets with higher \( \ell_{\text{max}} \) as for example Planck,\(^ 1 \) together with the unknown effect that different systematics from the instrument and background residuals might have on the estimates, motivated the search for new estimators based on different tools such as the SMHW described in this paper, the binned bispectrum (Bucher, van Tent & Carvalho 2010), the general modal expansion and polyspectra estimation (Fergusson et al. 2010b; Fergusson & Shellard 2011), the needlets (Marinucci et al. 2008; Pietrobon et al. 2009; Rudjord et al. 2009; Donzelli et al. 2012), the HEALPIX wavelet (Casaponsa et al. 2011a), neural networks (Casaponsa et al. 2011b) or a Bayesian approach (Elsner & Wandelt 2010; Elsner, Wandelt & Schneider 2010) among others.

In a previous paper (Curto et al. 2011a), we described the main features of the wavelet estimator based on the cubic statistics constructed from the SMHW coefficient maps. Those cubic terms were written as a function of the non-linear coupling parameter \( f_{nl} \) and the bispectrum of the primordial non-Gaussianity. In that paper,
we also showed that the power of the method to detect $f_{\text{gal}}$, that is the variance of this parameter $\sigma^2(f_{\text{gal}})$, matches that of the direct bispectrum-based estimators for ideal conditions (full sky and isotropic noise) and realistic conditions (partial sky coverage and anisotropic noise). The wavelet estimator variance was obtained in two different ways: through the Fisher matrix and by means of Monte Carlo (MC) simulations, providing very similar results. A remarkable result of these works is the fact that the wavelet estimator is, in practice, able to reach optimality on the $f_{\text{gal}}$ estimation without including any linear term correction. However, from several works (see for example Cremielli et al. 2006; Fergusson & Shellard 2011) it has been shown that in order to reach minimum variance, all the cubic estimators need a linear term correction. A recent work has solved this apparent controversy (Donzelli et al. 2012) by showing that in Wilkinson Microwave Anisotropy Probe (WMAP)\textsuperscript{2} anisotropy conditions, the linear term correction is nearly equivalent to the mean subtraction performed for each wavelet coefficient map in the wavelet estimator.

In this paper, we re-examine the main statistical properties of the wavelet estimator and show the conditions to reach optimality. We compute the linear term correction for the local, equilateral and orthogonal $f_{\text{gal}}$ shapes. In particular, we see that the linear term correction for the local case provides a 1 per cent reduction in the dispersion of the wavelet coefficients at scale $R$, while the correction for the other shapes is even smaller. Section 2 introduces the SMHW estimator, its variance and its linear correction. In Section 3, the estimator with its linear correction is applied to WMAP seven-year data for the local, equilateral and orthogonal shape. In Section 4, we explore the linear correction on Planck simulations at 143 GHz for the local shape, and in Section 5, the conclusions are presented.

2 THE WAVELET APPROACH

In this section, we present an approach for the $f_{\text{gal}}$ estimator based on the statistical properties of the cubic terms of the SMHW coefficients averaged over the sky. In this case, we exploit the property of the SMHW wavelet that performs a strong decorrelation of the data at distances larger than the wavelet resolution. The expected values of the cubic terms in the sky are obtained from the sum of a large number of almost independent elements, and therefore, its distribution will be close to Gaussian by the central limit theorem. We will first review the SMHW and its decorrelation properties, and then, we will construct the wavelet estimator based on those properties including the linear term correction.

2.1 The SMHW coefficients and their correlation

Detailed information about the SMHW and a (non-complete) list of applications to the CMB maps and cosmology can be found in Antoine & Vanderheynst (1998), Martínez-González et al. (2002), Cayón et al. (2003), Vielva, Martínez-González & Tucci (2006), Vielva (2007), McEwen et al. (2007), Martínez-González (2008), Zhang et al. (2011) and Yu et al. (2012).

Given a function $f(n)$ defined at a position $n$ on the sphere and a continuous wavelet family on that space $\Psi(n; b, R)$, we define the continuous wavelet transform as

$$w(R; b) = \int d n f(n) \Psi(n; b, R),$$

where $b$ is the position on the sky at which the wavelet coefficient is evaluated, $R$ is the scale of the wavelet and $\Psi_s(\theta; R) \equiv \Psi(n(\theta, \phi); 0, R)$ is given by

$$\Psi_s(\theta; R) = \frac{1}{\sqrt{2\pi}N(R)} \left[ 1 + \left( \frac{\gamma}{2} \right)^2 \left[ 2 - \left( \frac{\gamma}{R} \right)^2 \right] e^{-\gamma^2/2R^2} \right],$$

where

$$N(R) = R \left( 1 + \frac{R^2}{2} + \frac{R^4}{4} \right)^{1/2}$$

and

$$y = 2 \tan \left( \frac{\theta}{2} \right).$$

Considering a set of different angular scales $\{R_i\}$, we define a third-order statistic depending on three scales $\{i, j, k\}$ (Curto et al. 2009b)

$$q_{ijk} = \frac{1}{4\pi} \frac{1}{\sigma_i \sigma_j \sigma_k} \int d n w(R_i, n) w(R_j, n) w(R_k, n),$$

where $\sigma_i$ is the dispersion of the wavelet coefficient map $w(R_i, n)$. In the particular case of $R_i = 0$, $w(R_i, n) \equiv f(n)$. For a particular pixelization on the sphere, equation (5) can be written as

$$q_{ijk} = \frac{1}{N_{\text{pix}}} \sum_{p=0}^{N_{\text{pix}}-1} \frac{w(p)w(j)w(k)}{\sigma_i \sigma_j \sigma_k},$$

where $N_{\text{pix}}$ is the total number of pixels of the map, $N_{ijk}$ is the number of pixels available after combining the extended masks corresponding to these three scales $R_i, R_j$ and $R_k$ and $w(p) \equiv w(R_p, p) - \langle w(R_p) \rangle$ is the wavelet coefficient in the pixel $p$ evaluated at the scale $R_p$ after subtracting the mean value over the wavelet coefficient map outside its extended mask.

Using the properties of the wavelet, we may write the wavelet transform of the temperature map in the next form (Curto et al. 2011a)

$$u(R_i, n) = \sum_{l \text{ even}} c_{i l} \omega_l(R_i) Y_{l \text{ even}}(n).$$

Using the isotropic properties of the CMB and the properties of the wavelet, we can obtain the angular coefficient correlation $C_{ij}(\theta)$ between any pair of pixels $n$ and $n'$ separated by an angular distance $\cos(\theta)$ and for two angular scales $R_i$ and $R_j$:

$$C_{ij}(\theta) \equiv \langle u(R_i, n) u(R_j, n') \rangle = \sum_{\ell} \frac{2\ell + 1}{4\pi} C_{i \ell} \omega_{\ell}(R_i) \omega_{\ell}(R_j) P_\ell(\cos(\theta)).$$

where $\omega_{\ell}(R)$ is the window function of the wavelet at a scale $R$ and it is given by the harmonic transform of the mother wavelet of the SMHW (Martínez-González et al. 2002; Sanz et al. 2006). The dispersion of the wavelet coefficients at scale $R_i$ is simply given by

$$\sigma_i = C_{ii}(\theta = 0)^{1/2}.$$

In Fig. 1, we show the correlation of the wavelet coefficients as a function of the angular distance $\theta$ for several values of the resolution scale $R$. As can be seen, the SMHW produces an effective decorrelation of the signal at angular distances above the resolution scale $R$.

2.2 The wavelet estimator

Considering the strong decorrelation produced by the convolution of the SMHW on the temperature anisotropies, we can now apply the
central limit theorem to the cubic statistics defined in equation (5). Since the average value is calculated from the sum of a very large number of almost independent elements (of the order of the number of pixels in the sphere with size that of the resolution scale $R$), then its distribution should be very close to a Gaussian. This is actually seen in Fig. 2, where the distribution of the cubic terms for different SMHW scales is shown. These distributions have been obtained from MC simulations of Gaussian temperature anisotropies.

The previous results indicate that, for Gaussian temperature anisotropies, a good representation of the $n$-point distribution of the quantities $q_{ijk}$ can be given in terms of a multinormal distribution. Allowing now for the presence of weak non-Gaussianity for the temperature anisotropies (e.g. an amplitude for the primordial non-Gaussianity consistent with WMAP data), one can use the next likelihood for the $f_{nl}$ parameter:

$$L(f_{nl}) \propto e^{-\chi^2(f_{nl})/2},$$  \hspace{1cm} (9)

where $\chi^2(f_{nl})$ is given by

$$\chi^2(f_{nl}) = \sum_{ijk, rst} \left( q_{ijk}^{\text{obs}} - f_{nl} \alpha_{ijk} \right) C_{ijk, rst}^{-1} \left( q_{rst}^{\text{obs}} - f_{nl} \alpha_{rst} \right) ,$$  \hspace{1cm} (10)

where $q_{ijk}^{\text{obs}}$ are the cubic statistics corresponding to the observed data, $\alpha_{ijk} = \langle q_{ijk} f_{nl} \rangle$ and $C_{ijk, rst}$ is the covariance matrix of the cubic statistics. A further test to check that the $q_{ijk}$ are normally distributed can be done by considering the property that $\Delta \chi^2(f_{nl}) = \chi^2(f_{nl}) - \chi^2_{\text{min}}(f_{nl})$ is a $\chi^2$ distribution with one degree of freedom. In particular, $\Delta \chi^2(f_{nl}) = 1$ (4) should provide the 1 (2)σ or 68 per cent (95 per cent) confidence intervals for the $f_{nl}$ parameter. Using MC simulations, we have checked that this is the case for the $q_{ijk}$ statistics.
After straightforward calculation, it can be easily seen that the \( f_{nl} \) estimator in this case is given by

\[
\hat{f}_{nl} = \frac{\sum \alpha_{ijk} C_{ijk,L}^{-1} q_{rst}}{\sum \alpha_{ijk} C_{ijk,L}^{-1} q_{rst}},
\]

while that the variance of the \( \hat{f}_{nl} \) parameter in equation (11) is given by

\[
\sigma^2(\hat{f}_{nl}) = \frac{1}{\text{det}(\delta^2 f_{2,\text{linear}})} = \frac{1}{\sum \alpha_{ijk} C_{ijk,L}^{-1} q_{rst}}.
\]

This estimator has already been shown to be nearly optimal on \( \text{WMAP} \) data (Curto et al. 2009a,b, 2010, 2011a,b) without the need of subtracting any linear term. However, as stated in Donzelli et al. (2012), from all the possible cubic combinations of three Gaussian variables, the Wick polynomials are shown to have minimum variance. This implies that in order to have a strictly speaking minimum variance estimator, a linear term correction needs to be included. In fact the linear term subtraction is equivalent to the mean subtraction at each wavelet coefficient map (Donzelli et al. 2012) for low levels of anisotropy. This is indeed the procedure that has been followed in Curto et al. (2009a,b, 2010, 2011a,b), and it explains the competitive results obtained just by subtracting the mean using the estimator in equation (11).

The linear term correction for the wavelet estimator can be written as

\[
\hat{f}_{nl}^{(\text{total})} = \hat{f}_{nl}^{(\text{cubic})} - \hat{f}_{nl}^{(\text{linear})},
\]

where \( \hat{f}_{nl}^{(\text{cubic})} \) is given by equation (11) and \( \hat{f}_{nl}^{(\text{linear})} \) is

\[
\sigma^2(\hat{f}_{nl}) = \frac{1}{\text{det}(\delta^2 f_{2,\text{linear}})} = \frac{1}{\sum \alpha_{ijk} C_{ijk,L}^{-1} q_{rst}}.
\]

The best estimates of the local shape presented in Curto et al. (2011b) are \( f_{nl}^{(\text{cubic})} \). The two-point correlation matrices needed for the linear term correction have also been estimated with 64000 Gaussian simulations. This number of simulations is needed in order to achieve the required precision in the estimation of the correlation matrices.

We have applied the estimator to one set of 10000 Gaussian simulations and the \( \text{WMAP} \) data. The results are presented in Fig. 3 for the three considered shapes. In the left-hand panels, the red histograms correspond to the best-fitting \( f_{nl} \) values obtained with the cubic estimator and the black histograms correspond to the best-fitting \( f_{nl} \) values after the linear term correction. The vertical lines correspond to the actual \( \text{WMAP} \) data values estimated with the cubic estimator (red) and the linearly corrected estimator (black). In the right-hand panels, we compare the best-fitting \( f_{nl} \) values for the same set of Gaussian simulations. Note that both \( f_{nl}^{(\text{cubic})} \) and \( f_{nl}^{(\text{total})} \) are highly correlated and the deviations are not significant. Finally, in Tables 1–3 the previous results are summarized. We present the \( \text{WMAP} \) seven-year \( f_{nl} \) best-fitting values for the cubic estimator \( f_{nl}^{(\text{cubic})} \), the linear estimator \( f_{nl}^{(\text{linear})} \), and \( f_{nl}^{(\text{total})} \) for the clean and raw (uncleaned) maps. The Fisher \( f_{nl} \) error bar as described in section 25 of Curto et al. (2011a) is also provided. For each case, we observe a small reduction of the error bars when the linear term is included. The largest correction is introduced in the local shape, where \( \sigma \) is reduced from \( \sigma(f_{nl}) = 21.6 \) to \( 21.4 \) (i.e. a reduction of 1 per cent, in agreement with Donzelli et al. 2012). The correction for the other two cases, equilateral and orthogonal, is also negligible (about 0.2 and 0.1 per cent, respectively). This is in agreement with Creminelli et al. (2006) for the equilateral shape, where the standard deviations of \( f_{nl} \) without the linear term were found closer to the lower Fisher limit than in the local shape, suggesting a less important contribution of the linear term correction.

Our best-fitting values, computing \( \sigma(f_{nl}) \) with 10000 Gaussian simulations to characterize the errors, are presented below for the three shapes.

**Local form results:**

(i) \( f_{nl}^{(\text{cubic})} = 38.9 \pm 21.6 

(ii) \( f_{nl}^{(\text{total})} = 39.0 \pm 21.4 

**Equilateral form results:**

(i) \( f_{nl}^{(\text{cubic})} = -53.3 \pm 154.3 

(ii) \( f_{nl}^{(\text{total})} = -62.8 \pm 154.0 

**Orthogonal form results:**

(i) \( f_{nl}^{(\text{cubic})} = -155.1 \pm 115.1 

(ii) \( f_{nl}^{(\text{total})} = -159.8 \pm 115.1 

The average \( \langle q_{ijk} \rangle_{f_{nl}} \) is obtained using 10000 non-Gaussian simulations of the local shape generated by the procedure described in Elsner & Wandelt (2009), and publicly available at http://planck.mpg.de/cmb/fnl-simulations/. The best estimates of the local shape presented in Curto et al. (2011b) are \( f_{nl}^{(\text{cubic})} = 32.5 \pm 22.5 \). Note that in that work, a perturbative approach is considered to simulate the non-Gaussian simulations used to compute \( \langle q_{ijk} \rangle_{f_{nl}} \). The different approaches to simulate the non-Gaussianity and the statistical errors due to the finite number of non-Gaussian simulations explain the small differences between the error bars presented here and in that reference.
The effect of the linear term on the $f_{nl}$ wavelet estimator

Figure 3. WMAP seven-year data best-fitting $f_{nl}$ values using the cubic estimator (equation 11) and the estimator with the linear correction (equation 13) for the local (top), equilateral (middle) and orthogonal (bottom) shapes. In the left-hand panels, the histograms of the best-fitting $f_{nl}$ values with (dashed dark line) and without (solid red line) the linear term correction for each simulation are plotted. The vertical lines correspond to the values obtained with WMAP data. The right-hand panels show the corresponding correlation between the same estimates.

Table 1. Constraints on the $f_{nl}$ parameter for the local shape with and without the linear term correction. From left to right, the best-fitting values for the clean and the raw data maps, the mean, dispersion, 16, 84, 2.5 and 97.5 per cent quantiles, respectively, of the $f_{nl}$ distribution obtained with 10 000 Gaussian maps. The Fisher error bar obtained for this shape is $\sigma_{F}(f_{nl}) = 21.6$.

In order to check that the estimator has already reached optimality with the considered scales for the three shapes, we have computed $\sigma(f_{nl})$ for different subsets of scales (Fig. 4). We compare the $f_{nl}$ error bars for different minimum angular scales $R_{\min}$. To find the equivalent multipole $\ell$ range corresponding to each $R_{\min}$ see fig. 5 of Curto et al. (2011a). The three shapes reach minimum variance for $R_{\min} = 0$ arcmin.

The error bars of the equilateral and orthogonal shapes are also similar to the values obtained with the direct bispectrum estimator where $\sigma(f_{nl}) = 140$ for the equilateral shape and $\sigma(f_{nl}) = 104$ for the orthogonal shape (Komatsu et al. 2011). The slightly larger values ($\sim 9$ per cent) obtained from the dispersion of the $f_{nl}$ distribution corresponding to 10000 Gaussian simulations, $\sigma(f_{nl}) = 154$ and 115, respectively, are likely due to differences in the perturbative approach used to simulate the non-Gaussian signal of these two shapes (Curto et al. 2011b) or the statistical errors due to the finite number of non-Gaussian simulations.

4 APPLICATION TO PLANCK SIMULATIONS

We have computed the linear term correction to the cubic wavelet $f_{nl}$ estimator for the local shape using Planck simulations in order to forecast the amplitude of this correction on future Planck analyses. We do not consider the two other shapes (equilateral and orthogonal). From the results of the previous sections, we expect the correction for those cases to be even smaller.

For this analysis, we have considered a new set of angular scales that better suits the range of angular multipole which are cosmic variance dominated ($\ell_{\max} \sim 2000$). The list of angular scales is $R_0 = 0$, $R_1 = 1.3$, $R_2 = 2.1$, $R_3 = 3.4$, $R_4 = 5.4$, $R_5 = 8.7$, $R_6 = 13.9$, $R_7 = 22.3$, $R_8 = 35.6$, $R_9 = 57.0$, $R_{10} = 91.2$, $R_{11} = 146.0$, $R_{12} = 233.5$, $R_{13} = 373.6$, $R_{14} = 597.7$ and $R_{15} = 956.3$ arcmin. As a representative mask, we have used the available WMAP KQ75 mask (75 per cent of the sky). We have simulated the Planck 143 GHz channel using a fiducial CMB power spectrum that best fits WMAP 7-year data, $\ell_{\max} = 2048$ and a Gaussian beam with FWHM = 7.1 arcmin. The noise has been generated using an anisotropic $N_{\text{hits}}$ map computed from the scanning strategy of the Planck Sky Model (Delabrouille et al. 2012) and the noise sensitivity per pixel provided in the Planck Bluelook (using an average noise sensitivity for 14 months of $\sigma_{\text{noise}} = 2.2$ $\mu$K) in a square pixel whose size is the full width at half-maximum extent of the beam).

The cubic covariance matrix and the linear correlation matrices needed for the $f_{nl}$ estimator in equation (13) have been computed using two independent sets of 10000 Planck Gaussian simulations. The results corresponding to the analysis of an additional set of 1000 Gaussian maps are presented in Fig. 5. Note that for this simulated Planck level of anisotropy, $f_{nl}^{(\text{cubic})}$ and $f_{nl}^{(\text{total})}$ are also highly correlated. Finally in Table 4, the properties of the previous histograms are summarized. In particular, we see that using the cubic estimator $\sigma(f_{nl}) = 7.98$, and the linear term contribution reduces this error bar to $\sigma(f_{nl}) = 7.95$ (i.e. a negligible correction lower than 0.4 per cent).
on the wavelet coefficient maps for each angular scale (Curto et al. 2011a,b). We find that, in this case, the linear term correction only reduces the error bars about 1 per cent for the local case using the WMAP data. This correction is even smaller for the equilateral and orthogonal cases (0.2 and 0.1 per cent, respectively). The results presented in this paper are in agreement with the optimal results obtained with the wavelet estimator already published where the method was performed (Curto et al. 2009a,b, 2010, 2011a,b). Therefore, we conclude that the contribution of the linear term is negligible (≤1 per cent) for the SMHW estimator for the three considered cases. We have also explored the linear term correction for Planck simulations at the 143 GHz channel. Our results indicate that the correction for the local shape is lower than 0.4 per cent considering the expected levels of noise anisotropy for this channel and the WMAP KQ75 mask. From the results of WMAP data, we expect the correction for the equilateral and orthogonal shapes to be even smaller.
