General methods for synthesis and characterization

All reagents and solvents employed for the syntheses were of high purity grade and were purchased from Sigma-Aldrich Co., Merck, and SDS. $^1$H NMR spectra were recorded using a Bruker Avance 250, 400, 500 instruments and Me$_4$Si as an internal standard. Infrared spectra were recorded with Spectrum One FT-IR Spectroscopy instrument and UV/Vis/NIR spectra were measured using Cary 5000E Varian. ESR spectra were performed with a Bruker ESP 300 E equipped with a rectangular cavity T102 that works with an X-band (9.5 GHz). The solutions were degassed by argon bubbling before the measurements. LDI/TOF MS were recorded in a Bruker Ultraflex LDI-TOF spectrometer. Cyclic voltammetry measurements were obtained with a potentiostat 263a from EG&G Princeton Applied Research in a standard 3 electrodes cell. Dry solvents were used in the chemical reactions and in the cyclic voltammeters. The solvents used for optical spectroscopy and ESR measurements were of HPLC grade (ROMIL-SPS). In addition, for cyclic voltammetry experiments, CH$_2$Cl$_2$ was filtered over basic alumina to eliminate the acidic residues.

Synthesis of 2:

Scheme S1. Synthesis of the diformyl-TTF derivative 2.

**Compound 5:** Tributylphosphine (20.3 g, 0.1 mol) was added dropwise to a solution of 10 ml of carbon disulfide in 50 ml of tetrahydrofuran at -10°C under inert conditions and the deep maroon solution was stirred at room temperature for 1 hour. Next the mixture was cooled to -40°C and a solution of methyl propiolate (8.4 g, 0.1 mol) in 20 ml of tetrahydrofuran was added dropwise. The temperature was maintained between -30°C and -50°C during the addition. The solution was warmed to room temperature and stirred overnight. Finally solvents were evaporated under reduced pressure, the residue was stirred with ether to crash out the product that and was filtered and washed with Et$_2$O. Then the product was purified by column chromatography using CH$_2$Cl$_2$ as eluent to give 4.2 g (13 %) of the red microcrystalline powder 5. Characterization: $^1$H-NMR (250 MHz, CDCl$_3$, $\delta$(ppm): 7.35 (d, 2H, CH, $J$ = 7.34 Hz); 3.82 (s, 6H, CH$_3$). FT-IR ($\nu$ cm$^{-1}$): 2956 (w); 2922 (w); 2852 (w); 1712 (s, C=O); 1548 (s); 1434 (m); 1244 (s); 1199 (m); 1045 (m); 940 (m); 829 (m); 820 (m); 763 (m); 725 (m). LDI-TOF (positive mode): m/z (amu/e$^-$): 320.377 (M$^+$).

**Compound 6:** 30 ml of DIBAL-H (1 M in THF) was added dropwise to a solution of 5 (1 g, 3.12 mmol) in 60 ml of tetrahydrofuran cooled at -70°C under strict inert conditions. The color of the solution changes from red to yellow during the first hour of reaction. Then the solution was allowed to warm to room temperature and stirred overnight. The absence of TTF diester was confirmed by TLC and the reaction was hydrolyzed by the carefully addition of 10 ml of MeOH/HCl 12 M (3:1) mixture to the solution previously cooled with an ice bath. Then ether was
added to the mixture and the organic phase was washed with three portions of water (100 ml),
dried with anhydrous MgSO₄ and solvents were evaporated under reduced pressure. Finally the
product was purified by column chromatography of silica gel using a mixture of ether and
hexane to obtain 738 mg (85 %) of TTF diol 6 as a light brown solid. Characterization: ¹H-NMR
(250 MHz, DMSO-D₆, δ(ppm)): 6.52 (s, 2H); 5.48 (t, 2H, J = 5.9 Hz); 4.20 (d, 4H, J = 5.84 Hz,
CH₂OH). FT-IR (ν cm⁻¹): 3338 (s, OH); 3256 (s, OH); 2947 (m); 2918 (m); 2858 (m); 1587 (w);
1459 (m); 1443 (m); 1430 (m); 1369 (m); 1228 (m); 1092 (s); 1012 (s); 969 (m); 839 (w); 773
(w); 741 (w) 709 (w). LDI-TOF (positive mode): m/z (amu/e⁻): 263.926 (M⁺).

Compound 2: A solution of 6 (750 mg, 2.84 mmol) and 2 equivalents of selenium dioxide (630
mg) was heated under reflux for 2 h in dry dioxane (70 mL); the solution turned from yellow to
dark red. Cooling of the solution resulted in the formation of a black precipitate of elemental
selenium, which was filtered and washed thoroughly with dichloromethane. The solvent mixture
was then evaporated under reduced pressure to produce a dark red oil, which was purified by
SiO₂ column chromatography (eluent: hexane: Et₂O) to obtain 2 (295 mg, 40%) as a brownish
powder. Characterization: ¹H-NMR (250 MHz, DMSO-D₆, δ(ppm)): 9.54 (s, 2H, CHO); 8.27 and
8.28 (s, 2H). LDI-TOF (positive mode): m/z (amu/e⁻): 259.729 (M⁺).

Synthesis of diradical 1⁻:

Scheme S2: Final synthetic steps of diradical 1⁻. TBAOH = Tetrabutylammonium hydroxide.

Compound 4: 585 mg (0.67 mmol) of the phosphonated PTM derivative 3 were dissolved in 60
ml of anhydrous THF under strict inert conditions. The solution was cooled down to -78 °C.
Next, 150 mg (1.33 mmol) of potassium tert-butoxide were added and stirred for 20 minutes to
form the yellow-orange ylide. Then 101 mg (0.39 mmol) of 2 were added and the reaction was
warmed up to room temperature and stirred for 3 days. Then the mixture was washed with
water, dried with anhydrous MgSO₄ and solvents were evaporated under reduced pressure.
Finally the product was purified by column chromatography of silica gel using a mixture of ether
and hexane to obtain 250 mg (44 %) of 4 (E₁-Z) as a red powder. Characterization: ¹H-NMR
(250 MHz, CDCl₃, δ(ppm)): 7.22 (s, 1H, αH); 7.21 (s, 1H, αH); 6.32 (dd, J = 16.0, 2.5 Hz, 2H, CH=CH);
6.18 (dd, J = 16.1, 6.2 Hz, 2H CH=CH); 5.53 (s, 2H, TTF). FT-IR (ν cm⁻¹): 2956 (w); 2922 (w); 2855 (w);
1614 (m, CH=CH); 1528 (m); 1455 (m); 1369 (m); 1336 (s); 1296 (s); 1276 (w); 1238 (w); 1206 (w);
1137 (m); 944 (m); 863 (w); 826 (w); 808 (s); 778 (m) 751 (m); 719 (w); 693 (m). LDI-TOF (positive mode): m/z (amu/e⁻): 1704.559 (M⁺); (negative mode): 1704.147 (M⁻). Cyclic voltammetry (Bu₄NPF₆ 0.15 M in CH₂Cl₂ as electrolyte): E₁⁻=0.621 V; E½₂=1.103 V.
Diradical 1**: 70 mg (0.04 mmol) of 4 were dissolved in 20 ml of distilled THF and 100 μl (0.10 mmol) of TBAOH 1.0 M in MeOH were added and stirred for 3 h under Ar atmosphere. Then 20 mg (0.12 mmol) of AgNO₃ were added and immediately stirred for 10 minutes. The solution was concentrated and the product was purified by flash column chromatography of silica gel using hexane as eluent to produce 50 mg (71 %) of a brownish powder. Characterization: FT-IR (ν cm⁻¹): 2952 (w); 2922 (w); 2855 (w); 1603 (m, CH=CH); 1504 (m); 1460 (m); 1376 (w); 1355 (2); 1335 (s); 1320 (s); 1278 (m); 1259 (s); 1162 (m); 1138 (w); 1118 (w); 935 (s); 866 (w); 817 (m); 777 (m) 752 (m); 735 (m); 711 (m). UV-VIS-NIR (CH₂Cl₂, λmax in nm, ε in M⁻¹ cm⁻¹): 299 (30752); 325 (28506); 426 (6303); 522 (1087). LDI-TOF (positive mode): m/z (amu/e): 1700.947 [M]+; 1630.060 [M-70]+; (negative mode): 1704.913 [M]-; 1632.412 [M-70]-. Cyclic voltammetry (Bu₄NPF₆ 0.15 M in CH₂Cl₂ as electrolyte): E₁/₂ = -0.213 V; E₂/₂ = 0.591 V; E₃/₂ = 1.064 V. ESR (Toluene:CH₂Cl₂): g = 2.0027; a₁(H)=0.8 G (Half field at 1675 G).

Computational Details

Structures. The molecular geometries of the diradical (1\(^-\)) and triradical cation (1\(^{--+}\)) species have been optimized in their low-spin (LS, Singlet for 1\(^-\), Doublet for 1\(^{--+}\)) and high-spin states (HS, Triplet for 1\(^-\), Quadruplet for 1\(^{--+}\)), both for the Z and E isomers. All calculations have been performed at the UB3LYP/TZVP level using the D2 dispersion correction of Grimme\([S1]\) as implemented in Gaussian 09.\([S2]\) Dichloromethane solvent has been modelled using the PCM method.

Magnetic Properties. The magnetic exchange couplings (\(J_{AB}\)) have been evaluated on those structures at the same level of calculation. For 1\(^-\), we have calculated the energy of the triplet and Broken-Symmetry singlet and their energy difference has been directly used to compute \(J_1\) using the isotropic Heisenberg Hamiltonian \(\tilde{H} = -2 \sum_{A,B} J_{AB} \tilde{S}_A \tilde{S}_B\). In turn, for the triradical cation 1\(^{--+}\), we have calculated the energy of one quadruplet and three doublet states (one for each possible combination of two unpaired alpha and one beta electrons on the three magnetic units) and the resulting energy differences have been used to extract \(J_1 - 3\).

Optical Properties. The absorption spectra have been calculated on the optimized geometries of the Z isomer of the neutral diradical and cationic-triradical species in their HS state. We have used the UB3LYP/TZP scheme as implemented in ADF 2013.\([S3]\) Dichloromethane has been modelled using the PCM method.

Computational analysis of 1\(^-\) and 1\(^{--+}\):

Magnetic Properties. The ground state of 1\(^-\) is an open-shell singlet, with the two unpaired electrons localized in the PTM units (see Figure S15 and Table S1). They are coupled by an almost-negligible magnetic interaction (\(J_1\), see Figure S16 and Table S2 and), whose strength indicates that no magnetic ordering would be observed even at low temperatures and that the system would effectively behave as paramagnet, with ca. 75% population of triplet states. This is consistent with the CV measurements and with the observation of the \(\Delta m_s = 2\) transitions in the ESR spectrum.

In turn, the ground state of 1\(^{--+}\) is a doublet with three unpaired electrons localized in the TTF and PTM (x2) units (see Figure S17). The calculations indicate that the weak coupling between PTM units observed for 1\(^-\) is maintained, whereas moderately-strong antiferromagnetic (AFM) interactions appear between the oxidized TTF and each of the PTM moieties (\(J_2 \approx J_3 \approx -60\) cm\(^{-1}\)).

Finally, it is worth mentioning that the anionic monoradical compound 1\(^-\) has not been analyzed due to the well-known difficulty of describing mixed-valence states with DFT.\([S4-S6]\)

**Optical Properties.** TDDFT calculations shed some light on the optical properties of the studied compounds. Even if the position of the calculated bands displays a shift toward larger energies - smaller wavelengths - such analysis is useful to complement the rationalization of the spectra obtained experimentally. For compound $1^-$, the calculations predict three main bands (Table S3). One in the near-IR (1401 nm, oscillator strength $f_{osc} = 0.1$), corresponding to the charge transfer from the TTF HOMO to the PTM SUMO orbitals (see Figure S15). Since the two PTM units are not strictly equivalent, this transition appears as a double band (also 1338 nm, $f_{osc} = 0.03$). This computed band corresponds to the experimental band observed at 900 nm, and the red-shift is associated to (i) the accuracy of the calculation, which implies larger shifts in the low-energy region, and (ii) to the simplicity of our inspection, which does not account for the effects derived from the fast $E-Z$ isomerization. Two higher energy bands are also observed at 590 nm ($f_{osc} = 0.25$) and 520 nm ($f_{osc} = 0.44$). The first one corresponds to the transition from the TTF HOMO-1 to the PTM SUMO and the second one to the TTF HOMO to an unoccupied orbital delocalized over the Vinylene-PTM system.

### Table S3. Main bands of the absorption spectra computed for (a) $1^-$ and (b) $1^-$ in dichloromethane

<table>
<thead>
<tr>
<th>Band</th>
<th>Type</th>

</tr>
<tr>
<td>590 nm, $f_{osc} = 0.25$</td>
<td>TTF [HOMO-1] - PTM [SUMO]</td>
</tr>
<tr>
<td>1401 nm, $f_{osc} = 0.1$</td>
<td>TTF [HOMO] - PTM [SUMO]</td>
</tr>
</tbody>
</table>

Regarding $1^-$, our calculations yield two bright bands at 687 nm ($f_{osc} = 0.45$) and 510 nm ($f_{osc} = 0.65$) (see Table S3). The first one corresponds mainly (95%) to a transition from the TTF HOMO (HOMO-1 of the neutral TTF) to the PTM SUMO (see Figure S15). It is, thus, equivalent to the transition observed at 590 nm for the neutral compound. In turn, the second one is a mixture of several transitions, being dominant the one from the TTF SOMO (HOMO of the neutral TTF) to the Vinylene-PTM system, as observed for the neutral compound (band at 520 nm). As expected, the low-energy band observed for the neutral species disappears upon TTF oxidation.

**Structure.** The molecular geometries of the diradical ($1^-$) and triradical cation ($1^-$) species have been optimized in their low-spin (LS, Singlet for $1^-$, Doublet for $1^-$) and high-spin states (HS, Triplet for $1^-$, Quadruplet for $1^-$), both for the $Z$ and $E$ isomers and several conformations of the two vinylene bridges. Some of the values reported in Tables S4 and S5 have been used to extract the magnetic exchange couplings reported in Table S2.

### Table S4. Computed energy differences (in kcal/mol) of the Z- and E- isomers of $1^-$ in several conformations of the two vinylene bridges. The values are given with respect to the most stable one. The energy of the high-spin and low-spin states have been evaluated at each optimized structure.
