

The Standard Model of electroweak interactions

A. Pich

València, Spain

Abstract

Gauge invariance is a powerful tool to determine the dynamics of the electroweak and strong forces. The particle content, structure and symmetries of the Standard Model Lagrangian are discussed. Special emphasis is given to the many phenomenological tests which have established this theoretical framework as the Standard Theory of electroweak interactions.

1 Introduction

The Standard Model (SM) is a gauge theory, based on the symmetry group $SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$, which describes strong, weak, and electromagnetic interactions, via the exchange of the corresponding spin-1 gauge fields: eight massless gluons and one massless photon, respectively, for the strong and electromagnetic interactions, and three massive bosons, W^\pm and Z , for the weak interaction. The fermionic matter content is given by the known leptons and quarks, which are organized in a three-fold family structure:

$$\begin{bmatrix} \nu_e & u \\ e^- & d' \end{bmatrix}, \quad \begin{bmatrix} \nu_\mu & c \\ \mu^- & s' \end{bmatrix}, \quad \begin{bmatrix} \nu_\tau & t \\ \tau^- & b' \end{bmatrix}, \quad (1)$$

where (each quark appears in three different colours)

$$\begin{bmatrix} \nu_l & q_u \\ l^- & q_d \end{bmatrix} \equiv \left(\begin{array}{c} \nu_l \\ l^- \end{array} \right)_L, \quad \left(\begin{array}{c} q_u \\ q_d \end{array} \right)_L, \quad l_R^-, \quad q_{uR}, \quad q_{dR}, \quad (2)$$

plus the corresponding antiparticles. Thus, the left-handed fields are $SU(2)_L$ doublets, while their right-handed partners transform as $SU(2)_L$ singlets. The three fermionic families in Eq. (1) appear to have identical properties (gauge interactions); they differ only by their mass and their flavour quantum number.

The gauge symmetry is broken by the vacuum, which triggers the Spontaneous Symmetry Breaking (SSB) of the electroweak group to the electromagnetic subgroup:

$$SU(3)_C \otimes SU(2)_L \otimes U(1)_Y \xrightarrow{\text{SSB}} SU(3)_C \otimes U(1)_{\text{QED}}. \quad (3)$$

The SSB mechanism generates the masses of the weak gauge bosons, and gives rise to the appearance of a physical scalar particle in the model, the so-called Higgs. The fermion masses and mixings are also generated through the SSB.

The SM constitutes one of the most successful achievements in modern physics. It provides a very elegant theoretical framework, which is able to describe the known experimental facts in particle physics with high precision. These lectures [1] provide an introduction to the electroweak sector of the SM, i.e., the $SU(2)_L \otimes U(1)_Y$ part [2–5]. The strong $SU(3)_C$ piece is discussed in more detail in Ref. [6]. The power of the gauge principle is shown in Section 2, where the simpler Lagrangians of quantum electrodynamics and quantum chromodynamics are derived. The electroweak theoretical framework is presented in Sections 3 and 4, which discuss, respectively, the gauge structure and the SSB mechanism. Section 5 summarizes the present phenomenological status and shows the main precision tests performed at the Z peak. The flavour structure is discussed in Section 6, where knowledge of the quark mixing angles is briefly reviewed and the importance of \mathcal{CP} violation tests is emphasized. Finally, a few comments on open questions, to be investigated at future facilities, are given in the summary.

Some useful but more technical information has been collected in several appendices: a minimal amount of quantum field theory concepts are given in Appendix A; Appendix B summarizes the most important algebraic properties of $SU(N)$ matrices; and a short discussion on gauge anomalies is presented in Appendix C.

2 Gauge invariance

2.1 Quantum electrodynamics

Let us consider the Lagrangian describing a free Dirac fermion:

$$\mathcal{L}_0 = i\bar{\psi}(x)\gamma^\mu\partial_\mu\psi(x) - m\bar{\psi}(x)\psi(x). \quad (4)$$

\mathcal{L}_0 is invariant under *global* $U(1)$ transformations

$$\psi(x) \xrightarrow{U(1)} \psi'(x) \equiv \exp\{iQ\theta\}\psi(x), \quad (5)$$

where $Q\theta$ is an arbitrary real constant. The phase of $\psi(x)$ is then a pure convention-dependent quantity without physical meaning. However, the free Lagrangian is no longer invariant if one allows the phase transformation to depend on the space–time coordinate, i.e., under *local* phase redefinitions $\theta = \theta(x)$, because

$$\partial_\mu\psi(x) \xrightarrow{U(1)} \exp\{iQ\theta\}(\partial_\mu + iQ\partial_\mu\theta)\psi(x). \quad (6)$$

Thus, once a given phase convention has been adopted at the reference point x_0 , the same convention must be taken at all space–time points. This looks very unnatural.

The ‘gauge principle’ is the requirement that the $U(1)$ phase invariance should hold *locally*. This is only possible if one adds an extra piece to the Lagrangian, transforming in such a way as to cancel the $\partial_\mu\theta$ term in Eq. (6). The needed modification is completely fixed by the transformation (6): one introduces a new spin-1 (since $\partial_\mu\theta$ has a Lorentz index) field $A_\mu(x)$, transforming as

$$A_\mu(x) \xrightarrow{U(1)} A'_\mu(x) \equiv A_\mu(x) - \frac{1}{e}\partial_\mu\theta, \quad (7)$$

and defines the covariant derivative

$$D_\mu\psi(x) \equiv [\partial_\mu + ieQA_\mu(x)]\psi(x), \quad (8)$$

which has the required property of transforming like the field itself:

$$D_\mu\psi(x) \xrightarrow{U(1)} (D_\mu\psi)'(x) \equiv \exp\{iQ\theta\}D_\mu\psi(x). \quad (9)$$

The Lagrangian

$$\mathcal{L} \equiv i\bar{\psi}(x)\gamma^\mu D_\mu\psi(x) - m\bar{\psi}(x)\psi(x) = \mathcal{L}_0 - eQA_\mu(x)\bar{\psi}(x)\gamma^\mu\psi(x) \quad (10)$$

is then invariant under local $U(1)$ transformations.

The gauge principle has generated an interaction between the Dirac spinor and the gauge field A_μ , which is nothing else than the familiar vertex of Quantum Electrodynamics (QED). Note that the corresponding electromagnetic charge Q is completely arbitrary. If one wants A_μ to be a true propagating field, one needs to add a gauge-invariant kinetic term

$$\mathcal{L}_{\text{Kin}} \equiv -\frac{1}{4}F_{\mu\nu}(x)F^{\mu\nu}(x), \quad (11)$$

where $F_{\mu\nu} \equiv \partial_\mu A_\nu - \partial_\nu A_\mu$ is the usual electromagnetic field strength. A possible mass term for the gauge field, $\mathcal{L}_m = \frac{1}{2}m^2 A^\mu A_\mu$, is forbidden because it would violate gauge invariance; therefore, the photon field is predicted to be massless. Experimentally, we know that $m_\gamma < 6 \cdot 10^{-17}$ eV [7].

The total Lagrangian in Eqs. (10) and (11) gives rise to the well-known Maxwell equations:

$$\partial_\mu F^{\mu\nu} = J^\nu \equiv eQ\bar{\psi}\gamma^\nu\psi, \quad (12)$$

where J^ν is the fermion electromagnetic current. From a simple gauge-symmetry requirement, we have deduced the right QED Lagrangian, which leads to a very successful quantum field theory.

2.1.1 Lepton anomalous magnetic moments

Fig. 1: Feynman diagrams contributing to the lepton anomalous magnetic moment

The most stringent QED test comes from the high-precision measurements of the e [8] and μ [9] anomalous magnetic moments $a_l \equiv (g_l^\gamma - 2)/2$, where $\vec{\mu}_l \equiv g_l^\gamma (e/2m_l) \vec{S}_l$:

$$a_e = (1\,159\,652\,180.85 \pm 0.76) \cdot 10^{-12}, \quad a_\mu = (11\,659\,208.0 \pm 6.3) \cdot 10^{-10}. \quad (13)$$

To a measurable level, a_e arises entirely from virtual electrons and photons; these contributions are fully known to $O(\alpha^4)$ and some $O(\alpha^5)$ corrections have been already computed [10–14]. The impressive agreement achieved between theory and experiment has promoted QED to the level of the best theory ever built to describe Nature. The theoretical error is dominated by the uncertainty in the input value of the QED coupling $\alpha \equiv e^2/(4\pi)$. Turning things around, a_e provides the most accurate determination of the fine structure constant [15]:

$$\alpha^{-1} = 137.035\,999\,710 \pm 0.000\,000\,096. \quad (14)$$

The anomalous magnetic moment of the muon is sensitive to small corrections from virtual heavier states; compared to a_e , they scale with the mass ratio m_μ^2/m_e^2 . Electroweak effects from virtual W^\pm and Z bosons amount to a contribution of $(15.4 \pm 0.2) \cdot 10^{-10}$ [10, 11], which is larger than the present experimental precision. Thus a_μ allows one to test the entire SM. The main theoretical uncertainty comes from strong interactions. Since quarks have electric charge, virtual quark–antiquark pairs induce *hadronic vacuum polarization* corrections to the photon propagator [Fig. 1(c)]. Owing to the non-perturbative character of the strong interaction at low energies, the light-quark contribution cannot be reliably calculated at present. This effect can be extracted from the measurement of the cross-section $\sigma(e^+e^- \rightarrow \text{hadrons})$ and from the invariant-mass distribution of the final hadrons in τ decays, which unfortunately provide slightly different results [16–18]:

$$a_\mu^{\text{th}} = \begin{cases} (11\,659\,180.2 \pm 5.6) \cdot 10^{-10} & (e^+e^- \text{ data}), \\ (11\,659\,199.7 \pm 6.3) \cdot 10^{-10} & (\tau \text{ data}). \end{cases} \quad (15)$$

The quoted uncertainties include also the smaller *light-by-light scattering* contributions [Fig. 1(d)] [19]. The difference between the SM prediction and the experimental value (13) corresponds to 3.3σ (e^+e^-) or 0.9σ (τ). New precise e^+e^- and τ data sets are needed to settle the true value of a_μ^{th} .

Fig. 2: Tree-level Feynman diagram for the e^+e^- annihilation into hadrons

2.2 Quantum chromodynamics

2.2.1 Quarks and colour

The large number of known mesonic and baryonic states clearly signals the existence of a deeper level of elementary constituents of matter: *quarks*. Assuming that mesons are $M \equiv q\bar{q}$ states, while baryons have three quark constituents, $B \equiv qq\bar{q}$, one can nicely classify the entire hadronic spectrum. However, in order to satisfy the Fermi–Dirac statistics one needs to assume the existence of a new quantum number, *colour*, such that each species of quark may have $N_C = 3$ different colours: q^α , $\alpha = 1, 2, 3$ (red, green, blue). Baryons and mesons are then described by the colour-singlet combinations

$$B = \frac{1}{\sqrt{6}} \epsilon^{\alpha\beta\gamma} |q_\alpha q_\beta q_\gamma\rangle, \quad M = \frac{1}{\sqrt{3}} \delta^{\alpha\beta} |q_\alpha \bar{q}_\beta\rangle. \quad (16)$$

In order to avoid the existence of non-observed extra states with non-zero colour, one needs to further postulate that all asymptotic states are colourless, i.e., singlets under rotations in colour space. This assumption is known as the *confinement hypothesis*, because it implies the non-observability of free quarks: since quarks carry colour they are confined within colour-singlet bound states.

A direct test of the colour quantum number can be obtained from the ratio

$$R_{e^+e^-} \equiv \frac{\sigma(e^+e^- \rightarrow \text{hadrons})}{\sigma(e^+e^- \rightarrow \mu^+\mu^-)}. \quad (17)$$

The hadronic production occurs through $e^+e^- \rightarrow \gamma^*, Z^* \rightarrow q\bar{q} \rightarrow \text{hadrons}$ (Fig. 2). Since quarks are assumed to be confined, the probability to hadronize is just one; therefore, summing over all possible quarks in the final state, we can estimate the inclusive cross-section into hadrons. The electroweak production factors which are common with the $e^+e^- \rightarrow \gamma^*, Z^* \rightarrow \mu^+\mu^-$ process cancel in the ratio (17). At energies well below the Z peak, the cross-section is dominated by the γ -exchange amplitude; the ratio $R_{e^+e^-}$ is then given by the sum of the quark electric charges squared:

$$R_{e^+e^-} \approx N_C \sum_{f=1}^{N_f} Q_f^2 = \begin{cases} \frac{2}{3} N_C = 2, & (N_f = 3 : u, d, s) \\ \frac{10}{9} N_C = \frac{10}{3}, & (N_f = 4 : u, d, s, c) \\ \frac{11}{9} N_C = \frac{11}{3}, & (N_f = 5 : u, d, s, c, b) \end{cases}. \quad (18)$$

The measured ratio is shown in Fig. 3. Although the simple formula (18) cannot explain the complicated structure around the different quark thresholds, it gives the right average value of the cross-section (away from thresholds), provided that N_C is taken to be three. The agreement is better at larger energies. Notice that strong interactions have not been taken into account; only the confinement hypothesis has been used.

Electromagnetic interactions are associated with the fermion electric charges, while the quark flavours (up, down, strange, charm, bottom, top) are related to electroweak phenomena. The strong forces are flavour conserving and flavour independent. On the other side, the carriers of the electroweak interaction (γ, Z, W^\pm) do not couple to the quark colour. Thus it seems natural to take colour as the charge associated with the strong forces and try to build a quantum field theory based on it [20, 21].

Fig. 3: World data on the ratio $R_{e^+e^-}$ [7]. The broken lines show the naive quark model approximation with $N_C = 3$. The solid curve is the 3-loop perturbative QCD prediction.

2.2.2 Non-Abelian gauge symmetry

Let us denote q_f^α a quark field of colour α and flavour f . To simplify the equations, let us adopt a vector notation in colour space: $q_f^T \equiv (q_f^1, q_f^2, q_f^3)$. The free Lagrangian

$$\mathcal{L}_0 = \sum_f \bar{q}_f (i\gamma^\mu \partial_\mu - m_f) q_f \quad (19)$$

is invariant under arbitrary *global* $SU(3)_C$ transformations in colour space,

$$q_f^\alpha \longrightarrow (q_f^\alpha)' = U^\alpha_\beta q_f^\beta, \quad U U^\dagger = U^\dagger U = 1, \quad \det U = 1. \quad (20)$$

The $SU(3)_C$ matrices can be written in the form

$$U = \exp \left\{ i \frac{\lambda^a}{2} \theta_a \right\}, \quad (21)$$

where $\frac{1}{2} \lambda^a$ ($a = 1, 2, \dots, 8$) denote the generators of the fundamental representation of the $SU(3)_C$ algebra, and θ_a are arbitrary parameters. The matrices λ^a are traceless and satisfy the commutation relations

$$\left[\frac{\lambda^a}{2}, \frac{\lambda^b}{2} \right] = i f^{abc} \frac{\lambda^c}{2}, \quad (22)$$

with f^{abc} the $SU(3)_C$ structure constants, which are real and totally antisymmetric. Some useful properties of $SU(3)$ matrices are collected in Appendix B.

As in the QED case, we can now require the Lagrangian to be also invariant under *local* $SU(3)_C$ transformations, $\theta_a = \theta_a(x)$. To satisfy this requirement, we need to change the quark derivatives by covariant objects. Since we have now eight independent gauge parameters, eight different gauge bosons $G_a^\mu(x)$, the so-called *gluons*, are needed:

$$D^\mu q_f \equiv \left[\partial^\mu + ig_s \frac{\lambda^a}{2} G_a^\mu(x) \right] q_f \equiv [\partial^\mu + ig_s G^\mu(x)] q_f. \quad (23)$$

Notice that we have introduced the compact matrix notation

$$[G^\mu(x)]_{\alpha\beta} \equiv \left(\frac{\lambda^a}{2} \right)_{\alpha\beta} G_a^\mu(x). \quad (24)$$

Fig. 4: Interaction vertices of the QCD Lagrangian

We want $D^\mu q_f$ to transform in exactly the same way as the colour-vector q_f ; this fixes the transformation properties of the gauge fields:

$$D^\mu \longrightarrow (D^\mu)' = U D^\mu U^\dagger, \quad G^\mu \longrightarrow (G^\mu)' = U G^\mu U^\dagger + \frac{i}{g_s} (\partial^\mu U) U^\dagger. \quad (25)$$

Under an infinitesimal $SU(3)_C$ transformation,

$$\begin{aligned} q_f^\alpha &\longrightarrow (q_f^\alpha)' = q_f^\alpha + i \left(\frac{\lambda^a}{2} \right)_{\alpha\beta} \delta\theta_a q_f^\beta, \\ G_a^\mu &\longrightarrow (G_a^\mu)' = G_a^\mu - \frac{1}{g_s} \partial^\mu (\delta\theta_a) - f^{abc} \delta\theta_b G_c^\mu. \end{aligned} \quad (26)$$

The gauge transformation of the gluon fields is more complicated than the one obtained in QED for the photon. The non-commutativity of the $SU(3)_C$ matrices gives rise to an additional term involving the gluon fields themselves. For constant $\delta\theta_a$, the transformation rule for the gauge fields is expressed in terms of the structure constants f^{abc} ; thus, the gluon fields belong to the adjoint representation of the colour group (see Appendix B). Note also that there is a unique $SU(3)_C$ coupling g_s . In QED it was possible to assign arbitrary electromagnetic charges to the different fermions. Since the commutation relation (22) is non-linear, this freedom does not exist for $SU(3)_C$.

To build a gauge-invariant kinetic term for the gluon fields, we introduce the corresponding field strengths:

$$\begin{aligned} G^{\mu\nu}(x) &\equiv -\frac{i}{g_s} [D^\mu, D^\nu] = \partial^\mu G^\nu - \partial^\nu G^\mu + i g_s [G^\mu, G^\nu] \equiv \frac{\lambda^a}{2} G_a^{\mu\nu}(x), \\ G_a^{\mu\nu}(x) &= \partial^\mu G_a^\nu - \partial^\nu G_a^\mu - g_s f^{abc} G_b^\mu G_c^\nu. \end{aligned} \quad (27)$$

Under a gauge transformation,

$$G^{\mu\nu} \longrightarrow (G^{\mu\nu})' = U G^{\mu\nu} U^\dagger, \quad (28)$$

and the colour trace $\text{Tr}(G^{\mu\nu} G_{\mu\nu}) = \frac{1}{2} G_a^{\mu\nu} G_{\mu\nu}^a$ remains invariant.

Taking the proper normalization for the gluon kinetic term, we finally have the $SU(3)_C$ invariant Lagrangian of Quantum Chromodynamics (QCD):

$$\mathcal{L}_{\text{QCD}} \equiv -\frac{1}{4} G_a^{\mu\nu} G_{\mu\nu}^a + \sum_f \bar{q}_f (i\gamma^\mu D_\mu - m_f) q_f. \quad (29)$$

It is worth while to decompose the Lagrangian into its different pieces:

$$\mathcal{L}_{\text{QCD}} = -\frac{1}{4} (\partial^\mu G_a^\nu - \partial^\nu G_a^\mu) (\partial_\mu G_\nu^a - \partial_\nu G_\mu^a) + \sum_f \bar{q}_f^\alpha (i\gamma^\mu \partial_\mu - m_f) q_f^\alpha$$

Fig. 5: Two- and three-jet events from the hadronic Z boson decays $Z \rightarrow q\bar{q}$ and $Z \rightarrow q\bar{q}G$ (ALEPH) [22]

$$\begin{aligned}
 & - g_s G_a^\mu \sum_f \bar{q}_f^\alpha \gamma_\mu \left(\frac{\lambda^a}{2} \right)_{\alpha\beta} q_f^\beta \\
 & + \frac{g_s}{2} f^{abc} (\partial^\mu G_a^\nu - \partial^\nu G_a^\mu) G_\mu^b G_\nu^c - \frac{g_s^2}{4} f^{abc} f_{ade} G_b^\mu G_c^\nu G_\mu^d G_\nu^e.
 \end{aligned} \tag{30}$$

The first line contains the correct kinetic terms for the different fields, which give rise to the corresponding propagators. The colour interaction between quarks and gluons is given by the second line; it involves the $SU(3)_C$ matrices λ^a . Finally, owing to the non-Abelian character of the colour group, the $G_a^{\mu\nu} G_{\mu\nu}^a$ term generates the cubic and quartic gluon self-interactions shown in the last line; the strength of these interactions (Fig. 4) is given by the same coupling g_s which appears in the fermionic piece of the Lagrangian.

In spite of the rich physics contained in it, the Lagrangian (29) looks very simple because of its colour symmetry properties. All interactions are given in terms of a single universal coupling g_s , which is called the *strong coupling constant*. The existence of self-interactions among the gauge fields is a new feature that was not present in QED; it seems then reasonable to expect that these gauge self-interactions could explain properties like asymptotic freedom (strong interactions become weaker at short distances) and confinement (the strong forces increase at large distances), which do not appear in QED [6].

Without any detailed calculation, one can already extract qualitative physical consequences from \mathcal{L}_{QCD} . Quarks can emit gluons. At lowest order in g_s , the dominant process will be the emission of a single gauge boson; thus the hadronic decay of the Z should result in some $Z \rightarrow q\bar{q}G$ events, in addition to the dominant $Z \rightarrow q\bar{q}$ decays. Figure 5 clearly shows that 3-jet events, with the required kinematics, indeed appear in the LEP data. Similar events show up in e^+e^- annihilation into hadrons, away from the Z peak. The ratio between 3-jet and 2-jet events provides a simple estimate of the strength of the strong interaction at LEP energies ($s = M_Z^2$): $\alpha_s \equiv g_s^2/(4\pi) \sim 0.12$.

3 Electroweak unification

3.1 Experimental facts

Low-energy experiments have provided a large amount of information about the dynamics underlying flavour-changing processes. The detailed analysis of the energy and angular distributions in β decays, such as $\mu^- \rightarrow e^- \bar{\nu}_e \nu_\mu$ or $n \rightarrow p e^- \bar{\nu}_e$, made clear that only the left-handed (right-handed) fermion (antifermion) chiralities participate in those weak transitions; moreover, the strength of the interaction appears to be universal. This is further corroborated through the study of other processes like $\pi^- \rightarrow e^- \bar{\nu}_e$ or $\pi^- \rightarrow \mu^- \bar{\nu}_\mu$, which show that neutrinos have left-handed chiralities while anti-neutrinos are right-handed.

From neutrino scattering data, we learned the existence of different neutrino types ($\nu_e \neq \nu_\mu$) and that there are separately conserved lepton quantum numbers which distinguish neutrinos from antineutrinos; thus we observe the transitions $\bar{\nu}_e p \rightarrow e^+ n$, $\nu_e n \rightarrow e^- p$, $\bar{\nu}_\mu p \rightarrow \mu^+ n$ or $\nu_\mu n \rightarrow \mu^- p$, but we do not see processes like $\nu_e p \not\rightarrow e^+ n$, $\bar{\nu}_e n \not\rightarrow e^- p$, $\bar{\nu}_\mu p \not\rightarrow e^+ n$ or $\nu_\mu n \not\rightarrow e^- p$.

Together with theoretical considerations related to unitarity (a proper high-energy behaviour) and the absence of flavour-changing neutral-current transitions ($\mu^- \not\rightarrow e^- e^- e^+$), the low-energy information was good enough to determine the structure of the modern electroweak theory [23]. The intermediate vector bosons W^\pm and Z were theoretically introduced and their masses correctly estimated, before their experimental discovery. Nowadays, we have accumulated huge numbers of W^\pm and Z decay events, which bring much direct experimental evidence of their dynamical properties.

3.1.1 Charged currents

Fig. 6: Tree-level Feynman diagrams for $\mu^- \rightarrow e^- \bar{\nu}_e \nu_\mu$ and $\nu_\mu e^- \rightarrow \mu^- \nu_e$

The interaction of quarks and leptons with the W^\pm bosons (Fig. 6) exhibits the following features:

- Only left-handed fermions and right-handed antifermions couple to the W^\pm . Therefore, there is a 100% breaking of parity \mathcal{P} (left \leftrightarrow right) and charge conjugation \mathcal{C} (particle \leftrightarrow antiparticle). However, the combined transformation \mathcal{CP} is still a good symmetry.
- The W^\pm bosons couple to the fermionic doublets in Eq. (1), where the electric charges of the two fermion partners differ in one unit. The decay channels of the W^- are then:

$$W^- \rightarrow e^- \bar{\nu}_e, \mu^- \bar{\nu}_\mu, \tau^- \bar{\nu}_\tau, d' \bar{u}, s' \bar{c}. \quad (31)$$

Owing to the very high mass of the top quark [24], $m_t = 171 \text{ GeV} > M_W = 80.4 \text{ GeV}$, its on-shell production through $W^- \rightarrow b' \bar{t}$ is kinematically forbidden.

- All fermion doublets couple to the W^\pm bosons with the same universal strength.
- The doublet partners of the up, charm, and top quarks appear to be mixtures of the three quarks with charge $-\frac{1}{3}$:

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \mathbf{V} \begin{pmatrix} d \\ s \\ b \end{pmatrix}, \quad \mathbf{V} \mathbf{V}^\dagger = \mathbf{V}^\dagger \mathbf{V} = 1. \quad (32)$$

Thus, the weak eigenstates d' , s' , b' are different than the mass eigenstates d , s , b . They are related through the 3×3 unitary matrix \mathbf{V} , which characterizes flavour-mixing phenomena.

- The experimental evidence of neutrino oscillations shows that ν_e , ν_μ and ν_τ are also mixtures of mass eigenstates. However, the neutrino masses are tiny: $|m_{\nu_3}^2 - m_{\nu_2}^2| \sim 2.5 \cdot 10^{-3} \text{ eV}^2$, $m_{\nu_2}^2 - m_{\nu_1}^2 \sim 8 \cdot 10^{-5} \text{ eV}^2$ [7].

Fig. 7: Tree-level Feynman diagrams for $e^+e^- \rightarrow \mu^+\mu^-$ and $e^+e^- \rightarrow \nu\bar{\nu}$

3.1.2 Neutral currents

The neutral carriers of the electromagnetic and weak interactions have fermionic couplings (Fig. 7) with the following properties:

- All interacting vertices are flavour conserving. Both the γ and the Z couple to a fermion and its own antifermion, i.e., $\gamma f \bar{f}$ and $Z f \bar{f}$. Transitions of the type $\mu \not\leftrightarrow e\gamma$ or $Z \not\leftrightarrow e^\pm \mu^\mp$ have never been observed.
- The interactions depend on the fermion electric charge Q_f . Fermions with the same Q_f have exactly the same universal couplings. Neutrinos do not have electromagnetic interactions ($Q_\nu = 0$), but they have a non-zero coupling to the Z boson.
- Photons have the same interaction for both fermion chiralities, but the Z couplings are different for left-handed and right-handed fermions. The neutrino coupling to the Z involves only left-handed chiralities.
- There are three different light neutrino species.

3.2 The $SU(2)_L \otimes U(1)_Y$ theory

Using gauge invariance, we have been able to determine the right QED and QCD Lagrangians. To describe weak interactions, we need a more elaborated structure, with several fermionic flavours and different properties for left- and right-handed fields; moreover, the left-handed fermions should appear in doublets, and we would like to have massive gauge bosons W^\pm and Z in addition to the photon. The simplest group with doublet representations is $SU(2)$. We want to include also the electromagnetic interactions; thus we need an additional $U(1)$ group. The obvious symmetry group to consider is then

$$G \equiv SU(2)_L \otimes U(1)_Y, \quad (33)$$

where L refers to left-handed fields. We do not specify, for the moment, the meaning of the subindex Y since, as we shall see, the naive identification with electromagnetism does not work.

For simplicity, let us consider a single family of quarks, and introduce the notation

$$\psi_1(x) = \begin{pmatrix} u \\ d \end{pmatrix}_L, \quad \psi_2(x) = u_R, \quad \psi_3(x) = d_R. \quad (34)$$

Our discussion will also be valid for the lepton sector, with the identification

$$\psi_1(x) = \begin{pmatrix} \nu_e \\ e^- \end{pmatrix}_L, \quad \psi_2(x) = \nu_{eR}, \quad \psi_3(x) = e_R^-. \quad (35)$$

As in the QED and QCD cases, let us consider the free Lagrangian

$$\mathcal{L}_0 = i \bar{u}(x) \gamma^\mu \partial_\mu u(x) + i \bar{d}(x) \gamma^\mu \partial_\mu d(x) = \sum_{j=1}^3 i \bar{\psi}_j(x) \gamma^\mu \partial_\mu \psi_j(x). \quad (36)$$

\mathcal{L}_0 is invariant under global G transformations in flavour space:

$$\begin{aligned}\psi_1(x) &\xrightarrow{G} \psi'_1(x) \equiv \exp\{iy_1\beta\} U_L \psi_1(x), \\ \psi_2(x) &\xrightarrow{G} \psi'_2(x) \equiv \exp\{iy_2\beta\} \psi_2(x), \\ \psi_3(x) &\xrightarrow{G} \psi'_3(x) \equiv \exp\{iy_3\beta\} \psi_3(x),\end{aligned}\tag{37}$$

where the $SU(2)_L$ transformation

$$U_L \equiv \exp\left\{i \frac{\sigma_i}{2} \alpha^i\right\} \quad (i = 1, 2, 3)\tag{38}$$

acts only on the doublet field ψ_1 . The parameters y_i are called hypercharges, since the $U(1)_Y$ phase transformation is analogous to the QED one. The matrix transformation U_L is non-Abelian as in QCD. Notice that we have not included a mass term in Eq. (36) because it would mix the left- and right-handed fields [see Eq. (A.17)], therefore spoiling our symmetry considerations.

We can now require the Lagrangian to be also invariant under local $SU(2)_L \otimes U(1)_Y$ gauge transformations, i.e., with $\alpha^i = \alpha^i(x)$ and $\beta = \beta(x)$. In order to satisfy this symmetry requirement, we need to change the fermion derivatives by covariant objects. Since we have now four gauge parameters, $\alpha^i(x)$ and $\beta(x)$, four different gauge bosons are needed:

$$\begin{aligned}D_\mu \psi_1(x) &\equiv \left[\partial_\mu + i g \widetilde{W}_\mu(x) + i g' y_1 B_\mu(x) \right] \psi_1(x), \\ D_\mu \psi_2(x) &\equiv [\partial_\mu + i g' y_2 B_\mu(x)] \psi_2(x), \\ D_\mu \psi_3(x) &\equiv [\partial_\mu + i g' y_3 B_\mu(x)] \psi_3(x),\end{aligned}\tag{39}$$

where

$$\widetilde{W}_\mu(x) \equiv \frac{\sigma_i}{2} W_\mu^i(x)\tag{40}$$

denotes a $SU(2)_L$ matrix field. Thus we have the correct number of gauge fields to describe the W^\pm , Z and γ .

We want $D_\mu \psi_j(x)$ to transform in exactly the same way as the $\psi_j(x)$ fields; this fixes the transformation properties of the gauge fields:

$$B_\mu(x) \xrightarrow{G} B'_\mu(x) \equiv B_\mu(x) - \frac{1}{g'} \partial_\mu \beta(x),\tag{41}$$

$$\widetilde{W}_\mu \xrightarrow{G} \widetilde{W}'_\mu \equiv U_L(x) \widetilde{W}_\mu U_L^\dagger(x) + \frac{i}{g} \partial_\mu U_L(x) U_L^\dagger(x),\tag{42}$$

where $U_L(x) \equiv \exp\left\{i \frac{\sigma_i}{2} \alpha^i(x)\right\}$. The transformation of B_μ is identical to the one obtained in QED for the photon, while the $SU(2)_L$ W_μ^i fields transform in a way analogous to the gluon fields of QCD. Note that the ψ_j couplings to B_μ are completely free as in QED, i.e., the hypercharges y_j can be arbitrary parameters. Since the $SU(2)_L$ commutation relation is non-linear, this freedom does not exist for the W_μ^i : there is only a unique $SU(2)_L$ coupling g .

The Lagrangian

$$\mathcal{L} = \sum_{j=1}^3 i \bar{\psi}_j(x) \gamma^\mu D_\mu \psi_j(x)\tag{43}$$

is invariant under local G transformations. In order to build the gauge-invariant kinetic term for the gauge fields, we introduce the corresponding field strengths:

$$B_{\mu\nu} \equiv \partial_\mu B_\nu - \partial_\nu B_\mu,\tag{44}$$

$$\widetilde{W}_{\mu\nu} \equiv -\frac{i}{g} \left[\left(\partial_\mu + i g \widetilde{W}_\mu \right), \left(\partial_\nu + i g \widetilde{W}_\nu \right) \right] = \partial_\mu \widetilde{W}_\nu - \partial_\nu \widetilde{W}_\mu + i g [W_\mu, W_\nu], \quad (45)$$

$$\widetilde{W}_{\mu\nu} \equiv \frac{\sigma^i}{2} W_{\mu\nu}^i, \quad W_{\mu\nu}^i = \partial_\mu W_\nu^i - \partial_\nu W_\mu^i - g \epsilon^{ijk} W_\mu^j W_\nu^k. \quad (46)$$

$B_{\mu\nu}$ remains invariant under G transformations, while $\widetilde{W}_{\mu\nu}$ transforms covariantly:

$$B_{\mu\nu} \xrightarrow{G} B_{\mu\nu}, \quad \widetilde{W}_{\mu\nu} \xrightarrow{G} U_L \widetilde{W}_{\mu\nu} U_L^\dagger. \quad (47)$$

Therefore, the properly normalized kinetic Lagrangian is given by

$$\mathcal{L}_{\text{kin}} = -\frac{1}{4} B_{\mu\nu} B^{\mu\nu} - \frac{1}{2} \text{Tr} \left[\widetilde{W}_{\mu\nu} \widetilde{W}^{\mu\nu} \right] = -\frac{1}{4} B_{\mu\nu} B^{\mu\nu} - \frac{1}{4} W_{\mu\nu}^i W_i^{\mu\nu}. \quad (48)$$

Since the field strengths $W_{\mu\nu}^i$ contain a quadratic piece, the Lagrangian \mathcal{L}_{kin} gives rise to cubic and quartic self-interactions among the gauge fields. The strength of these interactions is given by the same $SU(2)_L$ coupling g which appears in the fermionic piece of the Lagrangian.

The gauge symmetry forbids the writing of a mass term for the gauge bosons. Fermionic masses are also not possible, because they would communicate the left- and right-handed fields, which have different transformation properties, and therefore would produce an explicit breaking of the gauge symmetry. Thus, the $SU(2)_L \otimes U(1)_Y$ Lagrangian in Eqs. (43) and (48) contains only massless fields.

3.3 Charged-current interaction

Fig. 8: Charged-current interaction vertices

The Lagrangian (43) contains interactions of the fermion fields with the gauge bosons,

$$\mathcal{L} \longrightarrow -g \bar{\psi}_1 \gamma^\mu \widetilde{W}_\mu \psi_1 - g' B_\mu \sum_{j=1}^3 y_j \bar{\psi}_j \gamma^\mu \psi_j. \quad (49)$$

The term containing the $SU(2)_L$ matrix

$$\widetilde{W}_\mu = \frac{\sigma^i}{2} W_\mu^i = \frac{1}{2} \begin{pmatrix} W_\mu^3 & \sqrt{2} W_\mu^\dagger \\ \sqrt{2} W_\mu & -W_\mu^3 \end{pmatrix} \quad (50)$$

gives rise to charged-current interactions with the boson field $W_\mu \equiv (W_\mu^1 + i W_\mu^2)/\sqrt{2}$ and its complex-conjugate $W_\mu^\dagger \equiv (W_\mu^1 - i W_\mu^2)/\sqrt{2}$ (Fig. 8). For a single family of quarks and leptons,

$$\mathcal{L}_{\text{CC}} = -\frac{g}{2\sqrt{2}} \left\{ W_\mu^\dagger [\bar{u} \gamma^\mu (1 - \gamma_5) d + \bar{\nu}_e \gamma^\mu (1 - \gamma_5) e] + \text{h.c.} \right\}. \quad (51)$$

The universality of the quark and lepton interactions is now a direct consequence of the assumed gauge symmetry. Note, however, that Eq. (51) cannot describe the observed dynamics, because the gauge bosons are massless and, therefore, give rise to long-range forces.

Fig. 9: Neutral-current interaction vertices

3.4 Neutral-current interaction

Equation (49) contains also interactions with the neutral gauge fields W_μ^3 and B_μ . We would like to identify these bosons with the Z and the γ . However, since the photon has the same interaction with both fermion chiralities, the singlet gauge boson B_μ cannot be equal to the electromagnetic field. That would require $y_1 = y_2 = y_3$ and $g'y_j = eQ_j$, which cannot be simultaneously true.

Since both fields are neutral, we can try with an arbitrary combination of them:

$$\begin{pmatrix} W_\mu^3 \\ B_\mu \end{pmatrix} \equiv \begin{pmatrix} \cos \theta_W & \sin \theta_W \\ -\sin \theta_W & \cos \theta_W \end{pmatrix} \begin{pmatrix} Z_\mu \\ A_\mu \end{pmatrix}. \quad (52)$$

The physical Z boson has a mass different from zero, which is forbidden by the local gauge symmetry. We will see in the next section how it is possible to generate non-zero boson masses, through the SSB mechanism. For the moment, we just assume that something breaks the symmetry, generating the Z mass, and that the neutral mass eigenstates are a mixture of the triplet and singlet $SU(2)_L$ fields. In terms of the fields Z and γ , the neutral-current Lagrangian is given by

$$\mathcal{L}_{\text{NC}} = - \sum_j \bar{\psi}_j \gamma^\mu \left\{ A_\mu \left[g \frac{\sigma_3}{2} \sin \theta_W + g' y_j \cos \theta_W \right] + Z_\mu \left[g \frac{\sigma_3}{2} \cos \theta_W - g' y_j \sin \theta_W \right] \right\} \psi_j. \quad (53)$$

In order to get QED from the A_μ piece, one needs to impose the conditions:

$$g \sin \theta_W = g' \cos \theta_W = e, \quad Y = Q - T_3, \quad (54)$$

where $T_3 \equiv \sigma_3/2$ and Q denotes the electromagnetic charge operator

$$Q_1 \equiv \begin{pmatrix} Q_{u/\nu} & 0 \\ 0 & Q_{d/e} \end{pmatrix}, \quad Q_2 = Q_{u/\nu}, \quad Q_3 = Q_{d/e}. \quad (55)$$

The first equality relates the $SU(2)_L$ and $U(1)_Y$ couplings to the electromagnetic coupling, providing the wanted unification of the electroweak interactions. The second identity fixes the fermion hypercharges in terms of their electric charge and weak isospin quantum numbers:

$$\text{Quarks: } y_1 = Q_u - \frac{1}{2} = Q_d + \frac{1}{2} = \frac{1}{6}, \quad y_2 = Q_u = \frac{2}{3}, \quad y_3 = Q_d = -\frac{1}{3},$$

$$\text{Leptons: } y_1 = Q_\nu - \frac{1}{2} = Q_e + \frac{1}{2} = -\frac{1}{2}, \quad y_2 = Q_\nu = 0, \quad y_3 = Q_e = -1.$$

A hypothetical right-handed neutrino would have both electric charge and weak hypercharge equal to zero. Since it would not couple either to the W^\pm bosons, such a particle would not have any kind of interaction (sterile neutrino). For aesthetic reasons, we shall not consider right-handed neutrinos any longer.

Using the relations (54), the neutral-current Lagrangian can be written as

$$\mathcal{L}_{\text{NC}} = \mathcal{L}_{\text{QED}} + \mathcal{L}_{\text{NC}}^Z, \quad (56)$$

Table 1: Neutral-current couplings

	u	d	ν_e	e
$2v_f$	$1 - \frac{8}{3}\sin^2\theta_W$	$-1 + \frac{4}{3}\sin^2\theta_W$	1	$-1 + 4\sin^2\theta_W$
$2a_f$	1	-1	1	-1

where

$$\mathcal{L}_{\text{QED}} = -e A_\mu \sum_j \bar{\psi}_j \gamma^\mu Q_j \psi_j \equiv -e A_\mu J_{\text{em}}^\mu \quad (57)$$

is the usual QED Lagrangian and

$$\mathcal{L}_{\text{NC}}^Z = -\frac{e}{2\sin\theta_W \cos\theta_W} J_Z^\mu Z_\mu \quad (58)$$

contains the interaction of the Z boson with the neutral fermionic current

$$J_Z^\mu \equiv \sum_j \bar{\psi}_j \gamma^\mu (\sigma_3 - 2\sin^2\theta_W Q_j) \psi_j = J_3^\mu - 2\sin^2\theta_W J_{\text{em}}^\mu. \quad (59)$$

In terms of the more usual fermion fields, $\mathcal{L}_{\text{NC}}^Z$ has the form (Fig. 9)

$$\mathcal{L}_{\text{NC}}^Z = -\frac{e}{2\sin\theta_W \cos\theta_W} Z_\mu \sum_f \bar{f} \gamma^\mu (v_f - a_f \gamma_5) f, \quad (60)$$

where $a_f = T_3^f$ and $v_f = T_3^f (1 - 4|Q_f| \sin^2\theta_W)$. Table 1 shows the neutral-current couplings of the different fermions.

3.5 Gauge self-interactions

Fig. 10: Gauge boson self-interaction vertices

In addition to the usual kinetic terms, the Lagrangian (48) generates cubic and quartic self-interactions among the gauge bosons (Fig. 10):

$$\begin{aligned} \mathcal{L}_3 = & ie \cot\theta_W \left\{ (\partial^\mu W^\nu - \partial^\nu W^\mu) W_\mu^\dagger Z_\nu - (\partial^\mu W^{\nu\dagger} - \partial^\nu W^{\mu\dagger}) W_\mu Z_\nu + W_\mu W_\nu^\dagger (\partial^\mu Z^\nu - \partial^\nu Z^\mu) \right\} \\ & + ie \left\{ (\partial^\mu W^\nu - \partial^\nu W^\mu) W_\mu^\dagger A_\nu - (\partial^\mu W^{\nu\dagger} - \partial^\nu W^{\mu\dagger}) W_\mu A_\nu + W_\mu W_\nu^\dagger (\partial^\mu A^\nu - \partial^\nu A^\mu) \right\}; \end{aligned} \quad (61)$$

$$\mathcal{L}_4 = -\frac{e^2}{2\sin^2\theta_W} \left\{ (W_\mu^\dagger W^\mu)^2 - W_\mu^\dagger W^{\mu\dagger} W_\nu W^\nu \right\} - e^2 \cot^2\theta_W \left\{ W_\mu^\dagger W^\mu Z_\nu Z^\nu - W_\mu^\dagger Z^\mu W_\nu Z^\nu \right\}$$

$$\begin{aligned}
& - e^2 \cot \theta_W \left\{ 2W_\mu^\dagger W^\mu Z_\nu A^\nu - W_\mu^\dagger Z^\mu W_\nu A^\nu - W_\mu^\dagger A^\mu W_\nu Z^\nu \right\} \\
& - e^2 \left\{ W_\mu^\dagger W^\mu A_\nu A^\nu - W_\mu^\dagger A^\mu W_\nu A^\nu \right\}.
\end{aligned}$$

Notice that at least a pair of charged W bosons are always present. The $SU(2)_L$ algebra does not generate any neutral vertex with only photons and Z bosons.

4 Spontaneous symmetry breaking

Fig. 11: Although Nicolás likes the symmetric food configuration, he must break the symmetry deciding which carrot is more appealing. In three dimensions, there is a continuous valley where Nicolás can move from one carrot to the next without effort.

So far, we have been able to derive charged- and neutral-current interactions of the type needed to describe weak decays; we have nicely incorporated QED into the same theoretical framework and, moreover, we have got additional self-interactions of the gauge bosons, which are generated by the non-Abelian structure of the $SU(2)_L$ group. Gauge symmetry also guarantees that we have a well-defined renormalizable Lagrangian. However, this Lagrangian has very little to do with reality. Our gauge bosons are massless particles; while this is fine for the photon field, the physical W^\pm and Z bosons should be quite heavy objects.

In order to generate masses, we need to break the gauge symmetry in some way; however, we also need a fully symmetric Lagrangian to preserve renormalizability. This dilemma may be solved by the possibility of getting non-symmetric results from an invariant Lagrangian.

Let us consider a Lagrangian, which

1. is invariant under a group G of transformations;
2. has a degenerate set of states with minimal energy, which transform under G as the members of a given multiplet.

If one of those states is arbitrarily selected as the ground state of the system, the symmetry is said to be spontaneously broken.

A well-known physical example is provided by a ferromagnet: although the Hamiltonian is invariant under rotations, the ground state has the spins aligned into some arbitrary direction; moreover, any higher-energy state, built from the ground state by a finite number of excitations, would share this anisotropy. In a Quantum Field Theory, the ground state is the vacuum; thus the SSB mechanism will appear when there is a symmetric Lagrangian, but a non-symmetric vacuum.

The horse in Fig. 11 illustrates in a very simple way the phenomenon of SSB. Although the left and right carrots are identical, Nicolás must take a decision if he wants to get food. What is important is not whether he goes left or right, which are equivalent options, but that the symmetry gets broken. In two dimensions (discrete left–right symmetry), after eating the first carrot Nicolás would need to make an effort to climb the hill in order to reach the carrot on the other side; however, in three dimensions (continuous rotation symmetry) there is a marvelous flat circular valley along which Nicolás can move from one carrot to the next without any effort.

The existence of flat directions connecting the degenerate states of minimal energy is a general property of the SSB of continuous symmetries. In a Quantum Field Theory it implies the existence of massless degrees of freedom.

4.1 Goldstone theorem

Fig. 12: Shape of the scalar potential for $\mu^2 > 0$ (left) and $\mu^2 < 0$ (right). In the second case there is a continuous set of degenerate vacua, corresponding to different phases θ , connected through a massless field excitation φ_2 .

Let us consider a complex scalar field $\phi(x)$, with Lagrangian

$$\mathcal{L} = \partial_\mu \phi^\dagger \partial^\mu \phi - V(\phi), \quad V(\phi) = \mu^2 \phi^\dagger \phi + h \left(\phi^\dagger \phi \right)^2. \quad (62)$$

\mathcal{L} is invariant under global phase transformations of the scalar field

$$\phi(x) \longrightarrow \phi'(x) \equiv \exp \{i\theta\} \phi(x). \quad (63)$$

In order to have a ground state the potential should be bounded from below, i.e., $h > 0$. For the quadratic piece there are two possibilities, shown in Fig. 12:

1. $\mu^2 > 0$: The potential has only the trivial minimum $\phi = 0$. It describes a massive scalar particle with mass μ and quartic coupling h .
2. $\mu^2 < 0$: The minimum is obtained for those field configurations satisfying

$$|\phi_0| = \sqrt{\frac{-\mu^2}{2h}} \equiv \frac{v}{\sqrt{2}} > 0, \quad V(\phi_0) = -\frac{h}{4} v^4. \quad (64)$$

Owing to the $U(1)$ phase-invariance of the Lagrangian, there is an infinite number of degenerate states of minimum energy, $\phi_0(x) = \frac{v}{\sqrt{2}} \exp \{i\theta\}$. By choosing a particular solution, $\theta = 0$ for example, as the ground state, the symmetry gets spontaneously broken. If we parametrize the excitations over the ground state as

$$\phi(x) \equiv \frac{1}{\sqrt{2}} [v + \varphi_1(x) + i \varphi_2(x)], \quad (65)$$

where φ_1 and φ_2 are real fields, the potential takes the form

$$V(\phi) = V(\phi_0) - \mu^2 \varphi_1^2 + h v \varphi_1 (\varphi_1^2 + \varphi_2^2) + \frac{h}{4} (\varphi_1^2 + \varphi_2^2)^2. \quad (66)$$

Thus φ_1 describes a massive state of mass $m_{\varphi_1}^2 = -2\mu^2$, while φ_2 is massless.

The first possibility ($\mu^2 > 0$) is just the usual situation with a single ground state. The other case, with SSB, is more interesting. The appearance of a massless particle when $\mu^2 < 0$ is easy to understand: the field φ_2 describes excitations around a flat direction in the potential, i.e., into states with the same energy as the chosen ground state. Since those excitations do not cost any energy, they obviously correspond to a massless state.

The fact that there are massless excitations associated with the SSB mechanism is a completely general result, known as the Goldstone theorem [25]: if a Lagrangian is invariant under a continuous symmetry group G , but the vacuum is only invariant under a subgroup $H \subset G$, then there must exist as many massless spin-0 particles (Goldstone bosons) as broken generators (i.e., generators of G which do not belong to H).

4.2 The Higgs–Kibble mechanism

At first sight, the Goldstone theorem has very little to do with our mass problem; in fact, it makes it worse since we want massive states and not massless ones. However, something very interesting happens when there is a local gauge symmetry [26, 27].

Let us consider [3] an $SU(2)_L$ doublet of complex scalar fields

$$\phi(x) \equiv \begin{pmatrix} \phi^{(+)}(x) \\ \phi^{(0)}(x) \end{pmatrix}. \quad (67)$$

The gauged scalar Lagrangian of the Goldstone model in Eq. (62),

$$\mathcal{L}_S = (D_\mu \phi)^\dagger D^\mu \phi - \mu^2 \phi^\dagger \phi - h (\phi^\dagger \phi)^2 \quad (h > 0, \mu^2 < 0), \quad (68)$$

$$D^\mu \phi = \left[\partial^\mu + i g \widetilde{W}^\mu + i g' y_\phi B^\mu \right] \phi, \quad y_\phi = Q_\phi - T_3 = \frac{1}{2}, \quad (69)$$

is invariant under local $SU(2)_L \otimes U(1)_Y$ transformations. The value of the scalar hypercharge is fixed by the requirement of having the correct couplings between $\phi(x)$ and $A^\mu(x)$; i.e., the photon does not couple to $\phi^{(0)}$, and $\phi^{(+)}$ has the right electric charge.

The potential is very similar to the one considered before. There is a infinite set of degenerate states with minimum energy, satisfying

$$|\langle 0 | \phi^{(0)} | 0 \rangle| = \sqrt{\frac{-\mu^2}{2h}} \equiv \frac{v}{\sqrt{2}}. \quad (70)$$

Note that we have made explicit the association of the classical ground state with the quantum vacuum. Since the electric charge is a conserved quantity, only the neutral scalar field can acquire a vacuum expectation value. Once we choose a particular ground state, the $SU(2)_L \otimes U(1)_Y$ symmetry gets spontaneously broken to the electromagnetic subgroup $U(1)_{\text{QED}}$, which by construction still remains a true symmetry of the vacuum. According to the Goldstone theorem three massless states should then appear.

Now, let us parametrize the scalar doublet in the general form

$$\phi(x) = \exp \left\{ i \frac{\sigma_i}{2} \theta^i(x) \right\} \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v + H(x) \end{pmatrix}, \quad (71)$$

with four real fields $\theta^i(x)$ and $H(x)$. The crucial point is that the local $SU(2)_L$ invariance of the Lagrangian allows us to rotate away any dependence on $\theta^i(x)$. These three fields are precisely the would-be massless Goldstone bosons associated with the SSB mechanism.

The covariant derivative (69) couples the scalar multiplet to the $SU(2)_L \otimes U(1)_Y$ gauge bosons. If one takes the physical (unitary) gauge $\theta^i(x) = 0$, the kinetic piece of the scalar Lagrangian (68) takes the form:

$$(D_\mu \phi)^\dagger D^\mu \phi \xrightarrow{\theta^i=0} \frac{1}{2} \partial_\mu H \partial^\mu H + (v + H)^2 \left\{ \frac{g^2}{4} W_\mu^\dagger W^\mu + \frac{g^2}{8 \cos^2 \theta_W} Z_\mu Z^\mu \right\}. \quad (72)$$

The vacuum expectation value of the neutral scalar has generated a quadratic term for the W^\pm and the Z , i.e., those gauge bosons have acquired masses:

$$M_Z \cos \theta_W = M_W = \frac{1}{2} v g. \quad (73)$$

Therefore, we have found a clever way of giving masses to the intermediate carriers of the weak force. We just add \mathcal{L}_S to our $SU(2)_L \otimes U(1)_Y$ model. The total Lagrangian is invariant under gauge transformations, which guarantees the renormalizability of the associated Quantum Field Theory [28]. However, SSB occurs. The three broken generators give rise to three massless Goldstone bosons which, owing to the underlying local gauge symmetry, can be eliminated from the Lagrangian. Going to the unitary gauge, we discover that the W^\pm and the Z (but not the γ , because $U(1)_{\text{QED}}$ is an unbroken symmetry) have acquired masses, which are moreover related as indicated in Eq. (73). Notice that Eq. (52) has now the meaning of writing the gauge fields in terms of the physical boson fields with definite mass.

It is instructive to count the number of degrees of freedom (d.o.f.). Before the SSB mechanism, the Lagrangian contains massless W^\pm and Z bosons, i.e., $3 \times 2 = 6$ d.o.f., due to the two possible polarizations of a massless spin-1 field, and four real scalar fields. After SSB, the three Goldstone modes are ‘eaten’ by the weak gauge bosons, which become massive and, therefore, acquire one additional longitudinal polarization. We have then $3 \times 3 = 9$ d.o.f. in the gauge sector, plus the remaining scalar particle H , which is called the Higgs boson. The total number of d.o.f. remains of course the same.

4.3 Predictions

We have now all the needed ingredients to describe the electroweak interaction within a well-defined Quantum Field Theory. Our theoretical framework implies the existence of massive intermediate gauge bosons, W^\pm and Z . Moreover, the Higgs–Kibble mechanism has produced a precise prediction¹ for the W^\pm and Z masses, relating them to the vacuum expectation value of the scalar field through Eq. (73). Thus M_Z is predicted to be bigger than M_W in agreement with the measured masses [29, 30]:

$$M_Z = 91.1875 \pm 0.0021 \text{ GeV}, \quad M_W = 80.398 \pm 0.025 \text{ GeV}. \quad (74)$$

From these experimental numbers, one obtains the electroweak mixing angle

$$\sin^2 \theta_W = 1 - \frac{M_W^2}{M_Z^2} = 0.223. \quad (75)$$

We can easily get an independent estimate of $\sin^2 \theta_W$ from the decay $\mu^- \rightarrow e^- \bar{\nu}_e \nu_\mu$. The momentum transfer $q^2 = (p_\mu - p_{\nu_\mu})^2 = (p_e + p_{\nu_e})^2 \lesssim m_\mu^2$ is much smaller than M_W^2 . Therefore the

¹Note, however, that the relation $M_Z \cos \theta_W = M_W$ has a more general validity. It is a direct consequence of the symmetry properties of \mathcal{L}_S and does not depend on its detailed dynamics.

W propagator in Fig. 6 shrinks to a point and can be well approximated through a local four-fermion interaction, i.e.,

$$\frac{g^2}{M_W^2 - q^2} \approx \frac{g^2}{M_W^2} = \frac{4\pi\alpha}{\sin^2\theta_W M_W^2} \equiv 4\sqrt{2} G_F. \quad (76)$$

The measured muon lifetime, $\tau_\mu = (2.197019 \pm 0.000021) \cdot 10^{-6}$ s [31], provides a very precise determination of the Fermi coupling constant G_F :

$$\frac{1}{\tau_\mu} = \Gamma_\mu = \frac{G_F^2 m_\mu^5}{192 \pi^3} f(m_e^2/m_\mu^2) (1 + \delta_{\text{RC}}), \quad f(x) \equiv 1 - 8x + 8x^3 - x^4 - 12x^2 \log x. \quad (77)$$

Taking into account the radiative corrections δ_{RC} , which are known to $O(\alpha^2)$ [32, 33], one gets [31]:

$$G_F = (1.166371 \pm 0.000006) \cdot 10^{-5} \text{ GeV}^{-2}. \quad (78)$$

The measured values of $\alpha^{-1} = 137.035999710(96)$, M_W and G_F imply

$$\sin^2\theta_W = 0.215, \quad (79)$$

in very good agreement with Eq. (75). We shall see later that the small difference between these two numbers can be understood in terms of higher-order quantum corrections. The Fermi coupling also gives a direct determination of the electroweak scale, i.e., the scalar vacuum expectation value:

$$v = \left(\sqrt{2} G_F\right)^{-1/2} = 246 \text{ GeV}. \quad (80)$$

4.4 The Higgs boson

Fig. 13: Higgs couplings to the gauge bosons

The scalar Lagrangian in Eq. (68) has introduced a new scalar particle into the model: the Higgs H . In terms of the physical fields (unitary gauge), \mathcal{L}_S takes the form

$$\mathcal{L}_S = \frac{1}{4} h v^4 + \mathcal{L}_H + \mathcal{L}_{HG^2}, \quad (81)$$

where

$$\mathcal{L}_H = \frac{1}{2} \partial_\mu H \partial^\mu H - \frac{1}{2} M_H^2 H^2 - \frac{M_H^2}{2v} H^3 - \frac{M_H^2}{8v^2} H^4, \quad (82)$$

$$\mathcal{L}_{HG^2} = M_W^2 W_\mu^\dagger W^\mu \left\{ 1 + \frac{2}{v} H + \frac{H^2}{v^2} \right\} + \frac{1}{2} M_Z^2 Z_\mu Z^\mu \left\{ 1 + \frac{2}{v} H + \frac{H^2}{v^2} \right\} \quad (83)$$

and the Higgs mass is given by

$$M_H = \sqrt{-2\mu^2} = \sqrt{2h} v. \quad (84)$$

The Higgs interactions (Fig. 13) have a very characteristic form: they are always proportional to the mass (squared) of the coupled boson. All Higgs couplings are determined by M_H , M_W , M_Z , and the vacuum expectation value v .

So far the experimental searches for the Higgs have only provided a lower bound on its mass, corresponding to the exclusion of the kinematical range accessible at LEP and the Tevatron [7]:

$$M_H > 114.4 \text{ GeV} \quad (95\% \text{ C.L.}). \quad (85)$$

4.5 Fermion masses

Fig. 14: Fermionic coupling of the Higgs boson

A fermionic mass term $\mathcal{L}_m = -m \bar{\psi} \psi = -m (\bar{\psi}_L \psi_R + \bar{\psi}_R \psi_L)$ is not allowed, because it breaks the gauge symmetry. However, since we have introduced an additional scalar doublet into the model, we can write the following gauge-invariant fermion-scalar coupling:

$$\mathcal{L}_Y = -c_1 (\bar{u}, \bar{d})_L \begin{pmatrix} \phi^{(+)} \\ \phi^{(0)} \end{pmatrix} d_R - c_2 (\bar{u}, \bar{d})_L \begin{pmatrix} \phi^{(0)*} \\ -\phi^{(-)} \end{pmatrix} u_R - c_3 (\bar{\nu}_e, \bar{e})_L \begin{pmatrix} \phi^{(+)} \\ \phi^{(0)} \end{pmatrix} e_R + \text{h.c.}, \quad (86)$$

where the second term involves the \mathcal{C} -conjugate scalar field $\phi^c \equiv i \sigma_2 \phi^*$. In the unitary gauge (after SSB), this Yukawa-type Lagrangian takes the simpler form

$$\mathcal{L}_Y = -\frac{1}{\sqrt{2}} (v + H) \{c_1 \bar{d} d + c_2 \bar{u} u + c_3 \bar{e} e\}. \quad (87)$$

Therefore, the SSB mechanism generates also fermion masses:

$$m_d = c_1 \frac{v}{\sqrt{2}}, \quad m_u = c_2 \frac{v}{\sqrt{2}}, \quad m_e = c_3 \frac{v}{\sqrt{2}}. \quad (88)$$

Since we do not know the parameters c_i , the values of the fermion masses are arbitrary. Note, however, that all Yukawa couplings are fixed in terms of the masses (Fig. 14):

$$\mathcal{L}_Y = -\left(1 + \frac{H}{v}\right) \{m_d \bar{d} d + m_u \bar{u} u + m_e \bar{e} e\}. \quad (89)$$

5 Electroweak phenomenology

In the gauge and scalar sectors, the SM Lagrangian contains only four parameters: g , g' , μ^2 , and h . One could trade them for α , θ_W , M_W , and M_H . Alternatively, we can choose as free parameters:

$$G_F = (1.166371 \pm 0.000006) \cdot 10^{-5} \text{ GeV}^{-2} \quad [31],$$

$$\begin{aligned}\alpha^{-1} &= 137.035\,999\,710 \pm 0.000\,000\,096 \quad [15], \\ M_Z &= (91.1875 \pm 0.0021) \text{ GeV} \quad [29, 30]\end{aligned}\quad (90)$$

and the Higgs mass M_H . This has the advantage of using the three most precise experimental determinations to fix the interaction. The relations

$$\sin^2 \theta_W = 1 - \frac{M_W^2}{M_Z^2}, \quad M_W^2 \sin^2 \theta_W = \frac{\pi \alpha}{\sqrt{2} G_F} \quad (91)$$

determine then $\sin^2 \theta_W = 0.212$ and $M_W = 80.94$ GeV. The predicted M_W is in good agreement with the measured value in Eq. (74).

Fig. 15: Tree-level Feynman diagrams contributing to the W^\pm and Z decays

At tree level (Fig. 15), the decay widths of the weak gauge bosons can easily be computed. The W partial widths,

$$\Gamma(W^- \rightarrow \bar{\nu}_l l^-) = \frac{G_F M_W^3}{6\pi\sqrt{2}}, \quad \Gamma(W^- \rightarrow \bar{u}_i d_j) = N_C |\mathbf{V}_{ij}|^2 \frac{G_F M_W^3}{6\pi\sqrt{2}}, \quad (92)$$

are equal for all leptonic decay modes (up to small kinematical mass corrections). The quark modes involve also the colour quantum number $N_C = 3$ and the mixing factor \mathbf{V}_{ij} relating weak and mass eigenstates, $d'_i = \mathbf{V}_{ij} d_j$. The Z partial widths are different for each decay mode, since its couplings depend on the fermion charge:

$$\Gamma(Z \rightarrow \bar{f} f) = N_f \frac{G_F M_Z^3}{6\pi\sqrt{2}} (|v_f|^2 + |a_f|^2), \quad (93)$$

where $N_l = 1$ and $N_q = N_C$. Summing over all possible final fermion pairs, one predicts the total widths $\Gamma_W = 2.09$ GeV and $\Gamma_Z = 2.48$ GeV, in excellent agreement with the experimental values $\Gamma_W = (2.147 \pm 0.060)$ GeV and $\Gamma_Z = (2.4952 \pm 0.0023)$ GeV [29, 30].

The universality of the W couplings implies

$$\text{Br}(W^- \rightarrow \bar{\nu}_l l^-) = \frac{1}{3 + 2N_C} = 11.1\%, \quad (94)$$

where we have taken into account that the decay into the top quark is kinematically forbidden. Similarly, the leptonic decay widths of the Z are predicted to be $\Gamma_l \equiv \Gamma(Z \rightarrow l^+ l^-) = 84.85$ MeV. As shown in Table 2, these predictions are in good agreement with the measured leptonic widths, confirming the universality of the W and Z leptonic couplings. There is, however, an excess of the branching ratio $W \rightarrow \tau \bar{\nu}_\tau$ with respect to $W \rightarrow e \bar{\nu}_e$ and $W \rightarrow \mu \bar{\nu}_\mu$, which represents a 2.8σ effect [29, 30].

The universality of the leptonic W couplings can also be tested indirectly, through weak decays mediated by charged-current interactions. Comparing the measured decay widths of leptonic or semileptonic decays which differ only by the lepton flavour, one can test experimentally that the W interaction is indeed the same, i.e., that $g_e = g_\mu = g_\tau \equiv g$. As shown in Table 3, the present data verify the universality of the leptonic charged-current couplings to the 0.2% level.

Table 2: Measured values of $\text{Br}(W^- \rightarrow \bar{\nu}_l l^-)$ and $\Gamma(Z \rightarrow l^+ l^-)$ [29, 30]. The average of the three leptonic modes is shown in the last column (for a massless charged lepton l).

	e	μ	τ	l
$\text{Br}(W^- \rightarrow \bar{\nu}_l l^-)$ (%)	10.65 ± 0.17	10.59 ± 0.15	11.44 ± 0.22	10.84 ± 0.09
$\Gamma(Z \rightarrow l^+ l^-)$ (MeV)	83.92 ± 0.12	83.99 ± 0.18	84.08 ± 0.22	83.985 ± 0.086

Table 3: Experimental determinations of the ratios $g_l/g_{l'}$ [18, 34]

$\Gamma_{\tau \rightarrow \nu_\tau e \bar{\nu}_e} / \Gamma_{\mu \rightarrow \nu_\mu e \bar{\nu}_e}$	$\Gamma_{\tau \rightarrow \nu_\tau \pi} / \Gamma_{\pi \rightarrow \mu \bar{\nu}_\mu}$	$\Gamma_{\tau \rightarrow \nu_\tau K} / \Gamma_{K \rightarrow \mu \bar{\nu}_\mu}$	$\Gamma_{W \rightarrow \tau \bar{\nu}_\tau} / \Gamma_{W \rightarrow \mu \bar{\nu}_\mu}$	
$ g_\tau/g_\mu $	1.0004 ± 0.0022	0.996 ± 0.005	0.979 ± 0.017	1.039 ± 0.013
$\Gamma_{\tau \rightarrow \nu_\tau \mu \bar{\nu}_\mu} / \Gamma_{\tau \rightarrow \nu_\tau e \bar{\nu}_e}$	$\Gamma_{\pi \rightarrow \mu \bar{\nu}_\mu} / \Gamma_{\pi \rightarrow e \bar{\nu}_e}$	$\Gamma_{K \rightarrow \mu \bar{\nu}_\mu} / \Gamma_{K \rightarrow e \bar{\nu}_e}$	$\Gamma_{K \rightarrow \pi \mu \bar{\nu}_\mu} / \Gamma_{K \rightarrow \pi e \bar{\nu}_e}$	
$ g_\mu/g_e $	1.0000 ± 0.0020	1.0017 ± 0.0015	1.012 ± 0.009	1.0002 ± 0.0026
$\Gamma_{W \rightarrow \mu \bar{\nu}_\mu} / \Gamma_{W \rightarrow e \bar{\nu}_e}$	$ g_\tau/g_e $		$\Gamma_{W \rightarrow \tau \bar{\nu}_\tau} / \Gamma_{W \rightarrow e \bar{\nu}_e}$	
$ g_\mu/g_e $	0.997 ± 0.010	1.0004 ± 0.0023	1.036 ± 0.014	

Another interesting quantity is the Z decay width into invisible modes,

$$\frac{\Gamma_{\text{inv}}}{\Gamma_l} \equiv \frac{N_\nu \Gamma(Z \rightarrow \bar{\nu} \nu)}{\Gamma_l} = \frac{2 N_\nu}{(1 - 4 \sin^2 \theta_W)^2 + 1}, \quad (95)$$

which is usually normalized to the charged leptonic width. The comparison with the measured value, $\Gamma_{\text{inv}}/\Gamma_l = 5.942 \pm 0.016$ [29, 30], provides very strong experimental evidence for the existence of three different light neutrinos.

5.1 Fermion-pair production at the Z peak

Fig. 16: Tree-level contributions to $e^+e^- \rightarrow \bar{f}f$ and kinematical configuration in the centre-of-mass system

Additional information can be obtained from the study of the process $e^+e^- \rightarrow \gamma, Z \rightarrow \bar{f}f$ (Fig. 16). For unpolarized e^+ and e^- beams, the differential cross-section can be written, at lowest order, as

$$\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{8s} N_f \{A(1 + \cos^2 \theta) + B \cos \theta - h_f [C(1 + \cos^2 \theta) + D \cos \theta]\}, \quad (96)$$

where $h_f = \pm 1$ denotes the sign of the helicity of the produced fermion f , and θ is the scattering angle between e^- and f in the centre-of-mass system. Here,

$$A = 1 + 2 v_e v_f \text{Re}(\chi) + (v_e^2 + a_e^2)(v_f^2 + a_f^2) |\chi|^2,$$

$$\begin{aligned}
B &= 4a_e a_f \operatorname{Re}(\chi) + 8v_e a_e v_f a_f |\chi|^2, \\
C &= 2v_e a_f \operatorname{Re}(\chi) + 2(v_e^2 + a_e^2) v_f a_f |\chi|^2, \\
D &= 4a_e v_f \operatorname{Re}(\chi) + 4v_e a_e (v_f^2 + a_f^2) |\chi|^2,
\end{aligned} \tag{97}$$

and χ contains the Z propagator

$$\chi = \frac{G_F M_Z^2}{2\sqrt{2}\pi\alpha} \frac{s}{s - M_Z^2 + is\Gamma_Z/M_Z}. \tag{98}$$

The coefficients A , B , C and D can be experimentally determined by measuring the total cross-section, the forward–backward asymmetry, the polarization asymmetry, and the forward–backward polarization asymmetry, respectively:

$$\begin{aligned}
\sigma(s) &= \frac{4\pi\alpha^2}{3s} N_f A, & \mathcal{A}_{\text{FB}}(s) &\equiv \frac{N_F - N_B}{N_F + N_B} = \frac{3}{8} \frac{B}{A}, \\
\mathcal{A}_{\text{Pol}}(s) &\equiv \frac{\sigma^{(h_f=+1)} - \sigma^{(h_f=-1)}}{\sigma^{(h_f=+1)} + \sigma^{(h_f=-1)}} = -\frac{C}{A}, & & \tag{99} \\
\mathcal{A}_{\text{FB,Pol}}(s) &\equiv \frac{N_F^{(h_f=+1)} - N_F^{(h_f=-1)} - N_B^{(h_f=+1)} + N_B^{(h_f=-1)}}{N_F^{(h_f=+1)} + N_F^{(h_f=-1)} + N_B^{(h_f=+1)} + N_B^{(h_f=-1)}} = -\frac{3}{8} \frac{D}{A}.
\end{aligned}$$

Here, N_F and N_B denote the number of f 's emerging in the forward and backward hemispheres, respectively, with respect to the electron direction. The measurement of the final fermion polarization can be done for $f = \tau$ by measuring the distribution of the final τ decay products.

For $s = M_Z^2$, the real part of the Z propagator vanishes and the photon-exchange terms can be neglected in comparison with the Z -exchange contributions ($\Gamma_Z^2/M_Z^2 \ll 1$). Equations (99) become then,

$$\begin{aligned}
\sigma^{0,f} &\equiv \sigma(M_Z^2) = \frac{12\pi}{M_Z^2} \frac{\Gamma_e \Gamma_f}{\Gamma_Z^2}, & \mathcal{A}_{\text{FB}}^{0,f} &\equiv \mathcal{A}_{\text{FB}}(M_Z^2) = \frac{3}{4} \mathcal{P}_e \mathcal{P}_f, \\
\mathcal{A}_{\text{Pol}}^{0,f} &\equiv \mathcal{A}_{\text{Pol}}(M_Z^2) = \mathcal{P}_f, & \mathcal{A}_{\text{FB,Pol}}^{0,f} &\equiv \mathcal{A}_{\text{FB,Pol}}(M_Z^2) = \frac{3}{4} \mathcal{P}_e,
\end{aligned} \tag{100}$$

where Γ_f is the Z partial decay width into the $\bar{f}f$ final state, and

$$\mathcal{P}_f \equiv -A_f \equiv \frac{-2v_f a_f}{v_f^2 + a_f^2} \tag{101}$$

is the average longitudinal polarization of the fermion f , which only depends on the ratio of the vector and axial-vector couplings.

With polarized e^+e^- beams, which have been available at SLC, one can also study the left–right asymmetry between the cross-sections for initial left- and right-handed electrons, and the corresponding forward–backward left–right asymmetry:

$$\mathcal{A}_{\text{LR}}^0 \equiv \mathcal{A}_{\text{LR}}(M_Z^2) = \frac{\sigma_L(M_Z^2) - \sigma_R(M_Z^2)}{\sigma_L(M_Z^2) + \sigma_R(M_Z^2)} = -\mathcal{P}_e, \quad \mathcal{A}_{\text{FB,LR}}^{0,f} \equiv \mathcal{A}_{\text{FB,LR}}(M_Z^2) = -\frac{3}{4} \mathcal{P}_f. \tag{102}$$

At the Z peak, $\mathcal{A}_{\text{LR}}^0$ measures the average initial lepton polarization, \mathcal{P}_e , without any need for final particle identification, while $\mathcal{A}_{\text{FB,LR}}^{0,f}$ provides a direct determination of the final fermion polarization.

\mathcal{P}_f is a very sensitive function of $\sin^2 \theta_W$. Small higher-order corrections can produce large variations on the predicted lepton polarization because $|v_l| = \frac{1}{2} |1 - 4 \sin^2 \theta_W| \ll 1$. Therefore \mathcal{P}_l provides an interesting window to search for electroweak quantum effects.

Fig. 17: The photon vacuum polarization (left) generates a charge screening effect, making $\alpha(s)$ smaller at larger distances

5.2 QED and QCD corrections

Before trying to analyse the relevance of higher-order electroweak contributions, it is instructive to consider the numerical impact of the well-known QED and QCD corrections. The photon propagator gets vacuum polarization corrections, induced by virtual fermion–antifermion pairs. This kind of QED loop correction can be taken into account through a redefinition of the QED coupling, which depends on the energy scale. The resulting QED running coupling $\alpha(s)$ decreases at large distances. This can be intuitively understood as the charge screening generated by the virtual fermion pairs (Fig. 17). The physical QED vacuum behaves as a polarized dielectric medium. The huge difference between the electron and Z mass scales makes this quantum correction relevant at LEP energies [15, 29, 30]:

$$\alpha(m_e^2)^{-1} = 137.035\,999\,710\,(96) > \alpha(M_Z^2)^{-1} = 128.93 \pm 0.05. \quad (103)$$

The running effect generates an important change in Eq. (91). Since G_F is measured at low energies, while M_W is a high-energy parameter, the relation between both quantities is modified by vacuum-polarization contributions. Changing α by $\alpha(M_Z^2)$, one gets the corrected predictions:

$$\sin^2 \theta_W = 0.231, \quad M_W = 79.96 \text{ GeV}. \quad (104)$$

The experimental value of M_W is in the range between the two results obtained with either α or $\alpha(M_Z^2)$, showing its sensitivity to quantum corrections. The effect is more spectacular in the leptonic asymmetries at the Z peak. The small variation of $\sin^2 \theta_W$ from 0.212 to 0.231 induces a large shift on the vector Z coupling to charged leptons from $v_l = -0.076$ to -0.038 , changing the predicted average lepton polarization \mathcal{P}_l by a factor of two.

So far, we have treated quarks and leptons on an equal footing. However, quarks are strong-interacting particles. The gluonic corrections to the decays $Z \rightarrow \bar{q}q$ and $W^- \rightarrow \bar{u}_i d_j$ can be directly incorporated into the formulae given before by taking an ‘effective’ number of colours:

$$N_C \implies N_C \left\{ 1 + \frac{\alpha_s}{\pi} + \dots \right\} \approx 3.115, \quad (105)$$

where we have used the value of α_s at $s = M_Z^2$, $\alpha_s(M_Z^2) = 0.119 \pm 0.002$ [7, 35].

Note that the strong coupling also ‘runs’. However, the gluon self-interactions generate an anti-screening effect, through gluon-loop corrections to the gluon propagator, which spread out the QCD charge [6]. Since this correction is larger than the screening of the colour charge induced by virtual quark–antiquark pairs, the net result is that the strong coupling decreases at short distances. Thus QCD has the required property of asymptotic freedom: quarks behave as free particles when $Q^2 \rightarrow \infty$ [36, 37].

QCD corrections increase the probability of the Z and the W^\pm to decay into hadronic modes. Therefore, their leptonic branching fractions become smaller. The effect can be easily estimated from Eq. (94). The probability of the decay $W^- \rightarrow \bar{\nu}_e e^-$ gets reduced from 11.1% to 10.8%, improving the agreement with the measured value in Table 2.

5.3 Higher-order electroweak corrections

Fig. 18: Self-energy corrections to the gauge boson propagators

Quantum corrections offer the possibility to be sensitive to heavy particles, which cannot be kinematically accessed, through their virtual loop effects. In QED and QCD the vacuum polarization contribution of a heavy fermion pair is suppressed by inverse powers of the fermion mass. At low energies, the information on the heavy fermions is then lost. This ‘decoupling’ of the heavy fields happens in theories with only vector couplings and an exact gauge symmetry [38], where the effects generated by the heavy particles can always be reabsorbed into a redefinition of the low-energy parameters.

The SM involves, however, a broken chiral gauge symmetry. This has the very interesting implication of avoiding the decoupling theorem [38]. The vacuum polarization contributions induced by a heavy top generate corrections to the W^\pm and Z propagators (Fig. 18), which increase quadratically with the top mass [39]. Therefore, a heavy top does not decouple. For instance, with $m_t = 171$ GeV, the leading quadratic correction to the second relation in Eq. (91) amounts to a sizeable 3% effect. The quadratic mass contribution originates in the strong breaking of weak isospin generated by the top and bottom quark masses, i.e., the effect is actually proportional to $m_t^2 - m_b^2$.

Owing to an accidental $SU(2)_C$ symmetry of the scalar sector (the so-called custodial symmetry), the virtual production of Higgs particles does not generate any quadratic dependence on the Higgs mass at one loop [39]. The dependence on M_H is only logarithmic. The numerical size of the corresponding correction in Eq. (91) varies from a 0.1% to a 1% effect for M_H in the range from 100 to 1000 GeV.

Fig. 19: One-loop corrections to the $Z\bar{b}b$ vertex, involving a virtual top

Higher-order corrections to the different electroweak couplings are non-universal and usually smaller than the self-energy contributions. There is one interesting exception, the $Z\bar{b}b$ vertex (Fig. 19), which is sensitive to the top quark mass [40]. The $Z\bar{f}f$ vertex gets one-loop corrections where a virtual W^\pm is exchanged between the two fermionic legs. Since the W^\pm coupling changes the fermion flavour, the decays $Z \rightarrow \bar{d}d, \bar{s}s, \bar{b}b$ get contributions with a top quark in the internal fermionic lines, i.e., $Z \rightarrow \bar{t}t \rightarrow \bar{d}_i d_j$. Notice that this mechanism can also induce the flavour-changing neutral-current decays $Z \rightarrow \bar{d}_i d_j$ with $i \neq j$. These amplitudes are suppressed by the small CKM mixing factors $|\mathbf{V}_{tj}\mathbf{V}_{ti}^*|^2$. However, for the $Z \rightarrow \bar{b}b$ vertex, there is no suppression because $|\mathbf{V}_{tb}| \approx 1$.

The explicit calculation [40–43] shows the presence of hard m_t^2 corrections to the $Z \rightarrow \bar{b}b$ vertex. This effect can be easily understood [40] in non-unitary gauges where the unphysical charged scalar $\phi^{(\pm)}$ is present. The fermionic couplings of the charged scalar are proportional to the fermion masses; therefore the exchange of a virtual $\phi^{(\pm)}$ gives rise to a m_t^2 factor. In the unitary gauge, the charged scalar has been ‘eaten’ by the W^\pm field; thus the effect comes now from the exchange of a longitudinal W^\pm , with terms proportional to $q^\mu q^\nu$ in the propagator that generate fermion masses. Since the W^\pm

couples only to left-handed fermions, the induced correction is the same for the vector and axial-vector $Z\bar{b}b$ couplings and, for $m_t = 171$ GeV, amounts to a 1.6% reduction of the $Z \rightarrow \bar{b}b$ decay width [40].

The ‘non-decoupling’ present in the $Z\bar{b}b$ vertex is quite different from the one happening in the boson self-energies. The vertex correction is not dependent on the Higgs mass. Moreover, while any kind of new heavy particle coupling to the gauge bosons would contribute to the W and Z self-energies, the possible new physics contributions to the $Z\bar{b}b$ vertex are much more restricted and, in any case, different. Therefore, the independent experimental measurement of the two effects is very valuable in order to disentangle possible new physics contributions from the SM corrections. In addition, since the ‘non-decoupling’ vertex effect is related to W_L exchange, it is sensitive to the SSB mechanism.

5.4 Standard Model electroweak fit

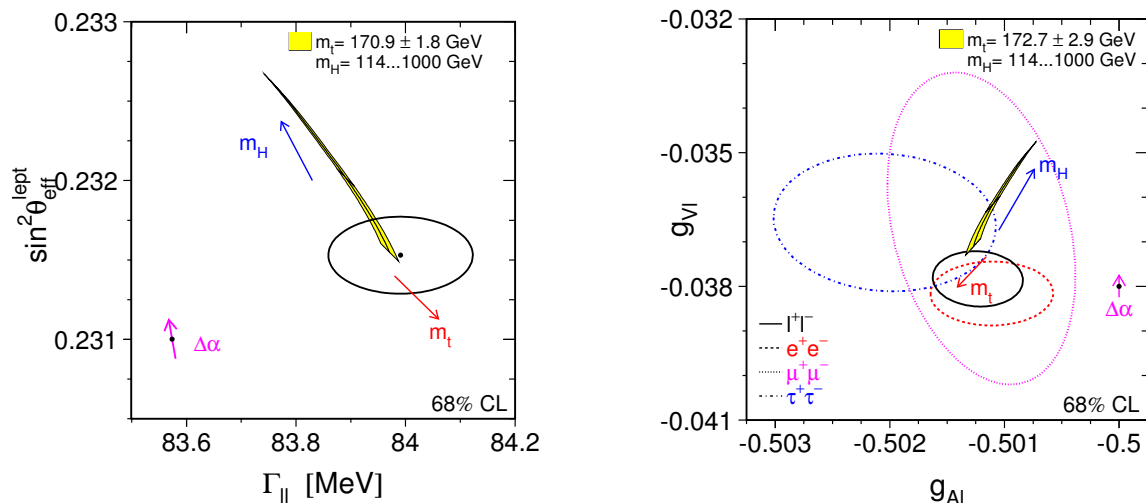

Fig. 20: Combined LEP and SLD measurements of $\sin^2 \theta_{\text{eff}}^{\text{lept}}$ and Γ_l (left) and the corresponding effective vector and axial-vector couplings v_l and a_l (right). The shaded region shows the SM prediction. The arrows point in the direction of increasing values of m_t and M_H . The point shows the predicted values if, among the electroweak radiative corrections, only the photon vacuum polarization is included. Its arrow indicates the variation induced by the uncertainty in $\alpha(M_Z^2)$ [29, 30].

The leptonic asymmetry measurements from LEP and SLD can all be combined to determine the ratios v_l/a_l of the vector and axial-vector couplings of the three charged leptons, or equivalently the effective electroweak mixing angle

$$\sin^2 \theta_{\text{eff}}^{\text{lept}} \equiv \frac{1}{4} \left(1 - \frac{v_l}{a_l} \right). \quad (106)$$

The sum $(v_l^2 + a_l^2)$ is derived from the leptonic decay widths of the Z , i.e., from Eq. (93) corrected with a multiplicative factor $(1 + \frac{3}{4} \frac{\alpha}{\pi})$ to account for final-state QED corrections. The signs of v_l and a_l are fixed by requiring $a_e < 0$.

The resulting 68% probability contours are shown in Fig. 20, which provides strong evidence of the electroweak radiative corrections. The good agreement with the SM predictions, obtained for low values of the Higgs mass, is lost if only the QED vacuum polarization contribution is taken into account, as indicated by the point with an arrow. Notice that the uncertainty induced by the input value of $\alpha(M_Z^2)^{-1} = 128.93 \pm 0.05$ is sizeable. The measured couplings of the three charged leptons confirm lepton universality in the neutral-current sector. The solid contour combines the three measurements assuming universality.

Fig. 21: Measurements of A_l , A_b (SLD) and $A_{\text{FB}}^{0,b}$. The arrows pointing to the left (right) show the variations of the SM prediction with $M_H = 300^{+700}_{-186}$ GeV ($m_t = 172.7 \pm 2.9$ GeV). The small arrow oriented to the left shows the additional uncertainty from $\alpha(M_Z^2)$ [29,30].

Fig. 22: The SM prediction of the ratios R_b and R_d [$R_q \equiv \Gamma(Z \rightarrow \bar{q}q)/\Gamma(Z \rightarrow \text{hadrons})$], as a function of the top mass. The measured value of R_b (vertical band) provides a determination of m_t [29, 30].

The neutrino couplings can also be determined from the invisible Z decay width, by assuming three identical neutrino generations with left-handed couplings, and fixing the sign from neutrino scattering data. Alternatively, one can use the SM prediction for Γ_{inv} to get a determination of the number of light neutrino flavours [29, 30]:

$$N_\nu = 2.9840 \pm 0.0082. \quad (107)$$

Figure 21 shows the measured values of A_l and A_b , together with the joint constraint obtained from $A_{\text{FB}}^{0,b}$ (diagonal band). The direct measurement of A_b at SLD agrees well with the SM prediction; however, a much lower value is obtained from the ratio $\frac{4}{3} A_{\text{FB}}^{0,b}/A_l$. This is the most significant discrepancy observed in the Z -pole data. Heavy quarks ($\frac{4}{3} A_{\text{FB}}^{0,b}/A_b$) seem to prefer a high value of the Higgs mass, while leptons (A_l) favour a light Higgs. The combined analysis prefers low values of M_H , because of the influence of A_l .

The strong sensitivity of the ratio $R_b \equiv \Gamma(Z \rightarrow \bar{b}b)/\Gamma(Z \rightarrow \text{hadrons})$ to the top quark mass is shown in Fig. 22. Owing to the $|V_{td}|^2$ suppression, such a dependence is not present in the analogous ratio R_d . Combined with all other electroweak precision measurements at the Z peak, R_b provides a determination of m_t in good agreement with the direct and most precise measurement at the Tevatron. This is shown in Fig. 23, which compares the information on M_W and m_t obtained at LEP1 and SLD, with the direct measurements performed at LEP2 and the Tevatron. A similar comparison for m_t and M_H is also shown. The lower bound on M_H obtained from direct searches excludes a large portion of the 68% C.L. allowed domain from precision measurements.

Taking all direct and indirect data into account, one obtains the best constraints on M_H . The global electroweak fit results in the $\Delta\chi^2 = \chi^2 - \chi_{\text{min}}^2$ curve shown in Fig. 24. The lower limit on M_H obtained from direct searches is close to the point of minimum χ^2 . At 95% C.L., one gets [29, 30]

$$114.4 \text{ GeV} < M_H < 144 \text{ GeV}. \quad (108)$$

The fit provides also a very accurate value of the strong coupling constant, $\alpha_s(M_Z^2) = 0.1186 \pm 0.0027$, in very good agreement with the world average value $\alpha_s(M_Z^2) = 0.119 \pm 0.002$ [7, 35]. The largest

Fig. 23: Comparison (left) of the direct measurements of M_W and m_t (LEP2 and Tevatron data) with the indirect determination through electroweak radiative corrections (LEP1 and SLD). Also shown in the SM relationship for the masses as function of M_H . The figure on the right makes the analogous comparison for m_t and M_H [29, 30].

Fig. 24: $\Delta\chi^2 = \chi^2 - \chi_{\min}^2$ versus M_H , from the global fit to the electroweak data. The vertical band indicates the 95% exclusion limit from direct searches [29, 30].

	Measurement	Fit	$(O^{\text{meas}} - O^{\text{fit}}) / \sigma^{\text{meas}}$

Fig. 25: Comparison between the measurements included in the combined analysis of the SM and the results from the global electroweak fit [29, 30]

discrepancy between theory and experiment occurs for $\mathcal{A}_{\text{FB}}^{0,b}$, with the fitted value being nearly 3σ larger than the measurement. As shown in Fig. 25, a good agreement is obtained for all other observables.

5.5 Gauge self-interactions

At tree level, the W -pair production process $e^+e^- \rightarrow W^+W^-$ involves three different contributions (Fig. 26), corresponding to the exchange of ν_e , γ and Z . The cross-section measured at LEP2 agrees very well with the SM predictions. As shown in Fig. 27, the ν_e -exchange contribution alone would lead to an unphysical growing of the cross-section at large energies and, therefore, would imply a violation of unitarity. Adding the γ -exchange contribution softens this behaviour, but a clear disagreement with the data persists. The Z -exchange mechanism, which involves the ZWW vertex, appears to be crucial in

Fig. 26: Feynman diagrams contributing to $e^+e^- \rightarrow W^+W^-$ and $e^+e^- \rightarrow ZZ$

order to explain the data.

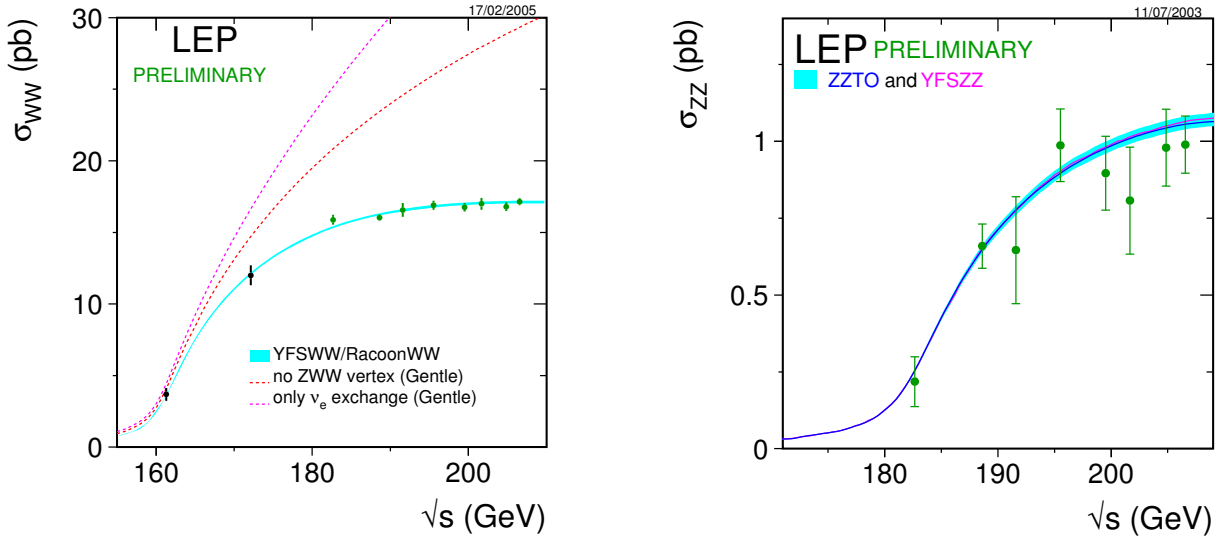

Fig. 27: Measured energy dependence of $\sigma(e^+e^- \rightarrow W^+W^-)$ (left) and $\sigma(e^+e^- \rightarrow ZZ)$ (right). The three curves shown for the W -pair production cross-section correspond to only the ν_e -exchange contribution (upper curve), ν_e exchange plus photon exchange (middle curve), and all contributions including also the ZWW vertex (lower curve). Only the e -exchange mechanism contributes to Z -pair production [29, 30].

Since the Z is electrically neutral, it does not interact with the photon. Moreover, the SM does not include any local ZZZ vertex. Therefore, the $e^+e^- \rightarrow ZZ$ cross-section only involves the contribution from e exchange. The agreement of the SM predictions with the experimental measurements in both production channels, W^+W^- and ZZ , provides a test of the gauge self-interactions. There is a clear signal of the presence of a ZWW vertex, with the predicted strength, and no evidence for any γZZ or ZZZ interactions. The gauge structure of the $SU(2)_L \otimes U(1)_Y$ theory is nicely confirmed by the data.

5.6 Higgs decays

The couplings of the Higgs boson are always proportional to some mass scale. The $Hf\bar{f}$ interaction grows linearly with the fermion mass, while the HWW and HZZ vertices are proportional to M_W^2 and M_Z^2 , respectively. Therefore, the most probable decay mode of the Higgs will be the one into the heaviest possible final state. This is clearly illustrated in Fig. 28. The $H \rightarrow b\bar{b}$ decay channel is by far the dominant one below the W^+W^- production threshold. When M_H is large enough to allow the production of a pair of gauge bosons, $H \rightarrow W^+W^-$ and $H \rightarrow ZZ$ become dominant. For $M_H > 2m_t$, the $H \rightarrow t\bar{t}$ decay width is also sizeable, although smaller than the WW and ZZ ones because of the different dependence of the corresponding Higgs coupling with the mass scale (linear instead of quadratic).

The total decay width of the Higgs grows with increasing values of M_H . The effect is very strong

Fig. 28: Branching fractions of the different Higgs decay modes (left) and total decay width of the Higgs boson (right) as function of M_H [44]

above the W^+W^- production threshold. A heavy Higgs becomes then very broad. At $M_H \sim 600$ GeV, the width is around 100 GeV; while for $M_H \sim 1$ TeV, Γ_H is already of the same size as the Higgs mass itself.

The design of the LHC detectors has taken into account all these very characteristic properties in order to optimize the future search for the Higgs boson.

6 Flavour dynamics

We have learned experimentally that there are six different quark flavours u, d, s, c, b, t , three different charged leptons e, μ, τ and their corresponding neutrinos ν_e, ν_μ, ν_τ . We can nicely include all these particles into the SM framework, by organizing them into three families of quarks and leptons, as indicated in Eqs. (1) and (2). Thus, we have three nearly identical copies of the same $SU(2)_L \otimes U(1)_Y$ structure, with masses as the only difference.

Let us consider the general case of N_G generations of fermions, and denote ν'_j, l'_j, u'_j, d'_j the members of the weak family j ($j = 1, \dots, N_G$), with definite transformation properties under the gauge group. Owing to the fermion replication, a large variety of fermion-scalar couplings are allowed by the gauge symmetry. The most general Yukawa Lagrangian has the form

$$\begin{aligned} \mathcal{L}_Y = & - \sum_{jk} \left\{ (\bar{u}'_j, \bar{d}'_j)_L \left[c_{jk}^{(d)} \begin{pmatrix} \phi^{(+)} \\ \phi^{(0)} \end{pmatrix} d'_{kR} + c_{jk}^{(u)} \begin{pmatrix} \phi^{(0)*} \\ -\phi^{(-)} \end{pmatrix} u'_{kR} \right] \right. \\ & \left. + (\bar{\nu}'_j, \bar{l}'_j)_L c_{jk}^{(l)} \begin{pmatrix} \phi^{(+)} \\ \phi^{(0)} \end{pmatrix} l'_{kR} \right\} + \text{h.c.}, \end{aligned} \quad (109)$$

where $c_{jk}^{(d)}, c_{jk}^{(u)}$ and $c_{jk}^{(l)}$ are arbitrary coupling constants.

After SSB, the Yukawa Lagrangian can be written as

$$\mathcal{L}_Y = - \left(1 + \frac{H}{v} \right) \{ \bar{\mathbf{d}}'_L \mathbf{M}'_d \mathbf{d}'_R + \bar{\mathbf{u}}'_L \mathbf{M}'_u \mathbf{u}'_R + \bar{\mathbf{l}}'_L \mathbf{M}'_l \mathbf{l}'_R + \text{h.c.} \}. \quad (110)$$

Here, \mathbf{d}' , \mathbf{u}' and \mathbf{l}' denote vectors in the N_G -dimensional flavour space, and the corresponding mass matrices are given by

$$(\mathbf{M}'_d)_{ij} \equiv c_{ij}^{(d)} \frac{v}{\sqrt{2}}, \quad (\mathbf{M}'_u)_{ij} \equiv c_{ij}^{(u)} \frac{v}{\sqrt{2}}, \quad (\mathbf{M}'_l)_{ij} \equiv c_{ij}^{(l)} \frac{v}{\sqrt{2}}. \quad (111)$$

The diagonalization of these mass matrices determines the mass eigenstates d_j, u_j and l_j , which are linear combinations of the corresponding weak eigenstates d'_j, u'_j and l'_j , respectively.

Fig. 29: Flavour-changing transitions through the charged-current couplings of the W^\pm bosons

The matrix \mathbf{M}'_d can be decomposed as² $\mathbf{M}'_d = \mathbf{H}_d \mathbf{U}_d = \mathbf{S}_d^\dagger \mathcal{M}_d \mathbf{S}_d \mathbf{U}_d$, where $\mathbf{H}_d \equiv \sqrt{\mathbf{M}'_d \mathbf{M}'_d{}^\dagger}$ is an Hermitian positive-definite matrix, while \mathbf{U}_d is unitary. \mathbf{H}_d can be diagonalized by a unitary matrix \mathbf{S}_d ; the resulting matrix \mathcal{M}_d is diagonal, Hermitian and positive definite. Similarly, one has $\mathbf{M}'_u = \mathbf{H}_u \mathbf{U}_u = \mathbf{S}_u^\dagger \mathcal{M}_u \mathbf{S}_u \mathbf{U}_u$ and $\mathbf{M}'_l = \mathbf{H}_l \mathbf{U}_l = \mathbf{S}_l^\dagger \mathcal{M}_l \mathbf{S}_l \mathbf{U}_l$. In terms of the diagonal mass matrices

$$\mathcal{M}_d = \text{diag}(m_d, m_s, m_b, \dots), \quad \mathcal{M}_u = \text{diag}(m_u, m_c, m_t, \dots), \quad \mathcal{M}_l = \text{diag}(m_e, m_\mu, m_\tau, \dots), \quad (112)$$

the Yukawa Lagrangian takes the simpler form

$$\mathcal{L}_Y = - \left(1 + \frac{H}{v} \right) \{ \bar{\mathbf{d}} \mathcal{M}_d \mathbf{d} + \bar{\mathbf{u}} \mathcal{M}_u \mathbf{u} + \bar{\mathbf{l}} \mathcal{M}_l \mathbf{l} \}, \quad (113)$$

where the mass eigenstates are defined by

$$\begin{aligned} \mathbf{d}_L &\equiv \mathbf{S}_d \mathbf{d}'_L, & \mathbf{u}_L &\equiv \mathbf{S}_u \mathbf{u}'_L, & \mathbf{l}_L &\equiv \mathbf{S}_l \mathbf{l}'_L, \\ \mathbf{d}_R &\equiv \mathbf{S}_d \mathbf{U}_d \mathbf{d}'_R, & \mathbf{u}_R &\equiv \mathbf{S}_u \mathbf{U}_u \mathbf{u}'_R, & \mathbf{l}_R &\equiv \mathbf{S}_l \mathbf{U}_l \mathbf{l}'_R. \end{aligned} \quad (114)$$

Note, that the Higgs couplings are proportional to the corresponding fermions masses.

Since, $\bar{\mathbf{f}}'_L \mathbf{f}'_L = \bar{\mathbf{f}}_L \mathbf{f}_L$ and $\bar{\mathbf{f}}'_R \mathbf{f}'_R = \bar{\mathbf{f}}_R \mathbf{f}_R$ ($f = d, u, l$), the form of the neutral-current part of the $SU(2)_L \otimes U(1)_Y$ Lagrangian does not change when expressed in terms of mass eigenstates. Therefore, there are no flavour-changing neutral currents in the SM (GIM mechanism [5]). This is a consequence of treating all equal-charge fermions on the same footing.

However, $\bar{\mathbf{u}}'_L \mathbf{d}'_L = \bar{\mathbf{u}}_L \mathbf{S}_u \mathbf{S}_d^\dagger \mathbf{d}_L \equiv \bar{\mathbf{u}}_L \mathbf{V} \mathbf{d}_L$. In general, $\mathbf{S}_u \neq \mathbf{S}_d$; thus, if one writes the weak eigenstates in terms of mass eigenstates, a $N_G \times N_G$ unitary mixing matrix \mathbf{V} , called the Cabibbo–Kobayashi–Maskawa (CKM) matrix [45, 46], appears in the quark charged-current sector:

$$\mathcal{L}_{CC} = - \frac{g}{2\sqrt{2}} \left\{ W_\mu^\dagger \left[\sum_{ij} \bar{u}_i \gamma^\mu (1 - \gamma_5) \mathbf{V}_{ij} d_j + \sum_l \bar{\nu}_l \gamma^\mu (1 - \gamma_5) l \right] + \text{h.c.} \right\}. \quad (115)$$

The matrix \mathbf{V} couples any ‘up-type’ quark with all ‘down-type’ quarks (Fig. 29).

If neutrinos are assumed to be massless, we can always redefine the neutrino flavours in such a way as to eliminate the analogous mixing in the lepton sector: $\bar{\nu}'_L \mathbf{l}'_L = \bar{\nu}'_L \mathbf{S}_l^\dagger \mathbf{l}_L \equiv \bar{\nu}_L \mathbf{l}_L$. Thus we have lepton-flavour conservation in the minimal SM without right-handed neutrinos. If sterile ν_R fields are included in the model, one would have an additional Yukawa term in Eq. (109), giving rise to a neutrino mass matrix $(\mathbf{M}'_\nu)_{ij} \equiv c_{ij}^{(\nu)} v / \sqrt{2}$. Thus the model could accommodate non-zero neutrino masses and lepton-flavour violation through a lepton mixing matrix \mathbf{V}_L analogous to the one present

²The condition $\det \mathbf{M}'_f \neq 0$ ($f = d, u, l$) guarantees that the decomposition $\mathbf{M}'_f = \mathbf{H}_f \mathbf{U}_f$ is unique: $\mathbf{U}_f \equiv \mathbf{H}_f^{-1} \mathbf{M}'_f$. The matrices \mathbf{S}_f are completely determined (up to phases) only if all diagonal elements of \mathbf{M}'_f are different. If there is some degeneracy, the arbitrariness of \mathbf{S}_f reflects the freedom to define the physical fields. If $\det \mathbf{M}'_f = 0$, the matrices \mathbf{U}_f and \mathbf{S}_f are not uniquely determined, unless their unitarity is explicitly imposed.

in the quark sector. Note, however, that the total lepton number $L \equiv L_e + L_\mu + L_\tau$ would still be conserved. We know experimentally that neutrino masses are tiny and there are strong bounds on lepton-flavour violating decays: $\text{Br}(\mu^\pm \rightarrow e^\pm e^+ e^-) < 1.0 \cdot 10^{-12}$ [47], $\text{Br}(\mu^\pm \rightarrow e^\pm \gamma) < 1.2 \cdot 10^{-11}$ [48], $\text{Br}(\tau^\pm \rightarrow \mu^\pm \gamma) < 4.5 \cdot 10^{-8}$ [49, 50] ... However, we do have a clear evidence of neutrino oscillation phenomena.

The fermion masses and the quark mixing matrix \mathbf{V} are all determined by the Yukawa couplings in Eq. (109). However, the coefficients $c_{ij}^{(f)}$ are not known; therefore we have a bunch of arbitrary parameters. A general $N_G \times N_G$ unitary matrix is characterized by N_G^2 real parameters: $N_G(N_G - 1)/2$ moduli and $N_G(N_G + 1)/2$ phases. In the case of \mathbf{V} , many of these parameters are irrelevant, because we can always choose arbitrary quark phases. Under the phase redefinitions $u_i \rightarrow e^{i\phi_i} u_i$ and $d_j \rightarrow e^{i\theta_j} d_j$, the mixing matrix changes as $\mathbf{V}_{ij} \rightarrow \mathbf{V}_{ij} e^{i(\theta_j - \phi_i)}$; thus, $2N_G - 1$ phases are unobservable. The number of physical free parameters in the quark-mixing matrix then gets reduced to $(N_G - 1)^2$: $N_G(N_G - 1)/2$ moduli and $(N_G - 1)(N_G - 2)/2$ phases.

In the simpler case of two generations, \mathbf{V} is determined by a single parameter. One then recovers the Cabibbo rotation matrix [45]

$$\mathbf{V} = \begin{pmatrix} \cos \theta_C & \sin \theta_C \\ -\sin \theta_C & \cos \theta_C \end{pmatrix}. \quad (116)$$

With $N_G = 3$, the CKM matrix is described by three angles and one phase. Different (but equivalent) representations can be found in the literature. The Particle data Group [7] advocates the use of the following one as the ‘standard’ CKM parametrization:

$$\mathbf{V} = \begin{bmatrix} c_{12} c_{13} & s_{12} c_{13} & s_{13} e^{-i\delta_{13}} \\ -s_{12} c_{23} - c_{12} s_{23} s_{13} e^{i\delta_{13}} & c_{12} c_{23} - s_{12} s_{23} s_{13} e^{i\delta_{13}} & s_{23} c_{13} \\ s_{12} s_{23} - c_{12} c_{23} s_{13} e^{i\delta_{13}} & -c_{12} s_{23} - s_{12} c_{23} s_{13} e^{i\delta_{13}} & c_{23} c_{13} \end{bmatrix}. \quad (117)$$

Here $c_{ij} \equiv \cos \theta_{ij}$ and $s_{ij} \equiv \sin \theta_{ij}$, with i and j being ‘generation’ labels ($i, j = 1, 2, 3$). The real angles θ_{12} , θ_{23} and θ_{13} can all be made to lie in the first quadrant, by an appropriate redefinition of quark field phases; then, $c_{ij} \geq 0$, $s_{ij} \geq 0$ and $0 \leq \delta_{13} \leq 2\pi$.

Notice that δ_{13} is the only complex phase in the SM Lagrangian. Therefore it is the only possible source of \mathcal{CP} -violation phenomena. In fact, it was for this reason that the third generation was assumed to exist [46], before the discovery of the b and the τ . With two generations, the SM could not explain the observed \mathcal{CP} violation in the K system.

6.1 Quark mixing

Fig. 30: Determinations of \mathbf{V}_{ij} are done in semileptonic quark decays (left) where a single quark current is present. Hadronic decay modes (right) involve two different quark currents and are more affected by QCD effects (gluons can couple everywhere).

Our knowledge of the charged-current parameters is unfortunately not so good as in the neutral-current case. In order to measure the CKM matrix elements, one needs to study hadronic weak decays

of the type $H \rightarrow H' l^- \bar{\nu}_l$ or $H \rightarrow H' l^+ \nu_l$, which are associated with the corresponding quark transitions $d_j \rightarrow u_i l^- \bar{\nu}_l$ and $u_i \rightarrow d_j l^+ \nu_l$ (Fig. 30). Since quarks are confined within hadrons, the decay amplitude

$$T[H \rightarrow H' l^- \bar{\nu}_l] \approx \frac{G_F}{\sqrt{2}} \mathbf{V}_{ij} \langle H' | \bar{u}_i \gamma^\mu (1 - \gamma_5) d_j | H \rangle [\bar{l} \gamma_\mu (1 - \gamma_5) \nu_l] \quad (118)$$

always involves an hadronic matrix element of the weak left current. The evaluation of this matrix element is a non-perturbative QCD problem, which introduces unavoidable theoretical uncertainties.

One usually looks for a semileptonic transition where the matrix element can be fixed at some kinematical point by a symmetry principle. This has the virtue of reducing the theoretical uncertainties to the level of symmetry-breaking corrections and kinematical extrapolations. The standard example is a $0^- \rightarrow 0^-$ decay such as $K \rightarrow \pi l \nu$, $D \rightarrow K l \nu$ or $B \rightarrow D l \nu$. Only the vector current can contribute in this case:

$$\langle P'(k') | \bar{u}_i \gamma^\mu d_j | P(k) \rangle = C_{PP'} \{ (k + k')^\mu f_+(t) + (k - k')^\mu f_-(t) \}. \quad (119)$$

Here, $C_{PP'}$ is a Clebsh–Gordan factor and $t = (k - k')^2 \equiv q^2$. The unknown strong dynamics is fully contained in the form factors $f_\pm(t)$. In the limit of equal quark masses, $m_{u_i} = m_{d_j} = 0$, the divergence of the vector current is zero; thus $q_\mu (\bar{u}_i \gamma^\mu d_j) = 0$, which implies $f_-(t) = 0$ and, moreover, $f_+(0) = 1$ to all orders in the strong coupling because the associated flavour charge is a conserved quantity³. Therefore, one only needs to estimate the corrections induced by the quark mass differences.

Since $q^\mu [\bar{l} \gamma_\mu (1 - \gamma_5) \nu_l] \sim m_l$, the contribution of $f_-(t)$ is kinematically suppressed in the electron and muon modes. The decay width can then be written as

$$\Gamma(P \rightarrow P' l \nu) = \frac{G_F^2 M_P^5}{192\pi^3} |\mathbf{V}_{ij}|^2 C_{PP'}^2 |f_+(0)|^2 \mathcal{I} (1 + \delta_{\text{RC}}), \quad (120)$$

where δ_{RC} is an electroweak radiative correction factor and \mathcal{I} denotes a phase-space integral, which in the $m_l = 0$ limit takes the form

$$\mathcal{I} \approx \int_0^{(M_P - M_{P'})^2} \frac{dt}{M_P^3} \lambda^{3/2}(t, M_P^2, M_{P'}^2) \left| \frac{f_+(t)}{f_+(0)} \right|^2. \quad (121)$$

The usual procedure to determine $|\mathbf{V}_{ij}|$ involves three steps:

1. Measure the shape of the t distribution. This fixes $|f_+(t)/f_+(0)|$ and therefore determines \mathcal{I} .
2. Measure the total decay width Γ . Since G_F is already known from μ decay, one gets then an experimental value for the product $|f_+(0)| |\mathbf{V}_{ij}|$.
3. Get a theoretical prediction for $f_+(0)$.

It is important to realize that theoretical input is always needed. Thus, the accuracy of the $|\mathbf{V}_{ij}|$ determination is limited by our ability to calculate the relevant hadronic input.

The conservation of the vector and axial-vector QCD currents in the massless quark limit allows for accurate determinations of the light-quark mixings $|\mathbf{V}_{ud}|$ and $|\mathbf{V}_{us}|$. The present values are shown in Table 4, which takes into account the recent changes in the $K \rightarrow \pi e^+ \nu_e$ data [7, 34] and the new $|\mathbf{V}_{us}|$ determinations from Cabibbo suppressed tau decays [52] and from the ratio of decay amplitudes $\Gamma(K^+ \rightarrow \mu^+ \bar{\nu}_\mu)/\Gamma(\pi^+ \rightarrow \mu^+ \bar{\nu}_\mu)$ [53–55]. Since $|\mathbf{V}_{ub}|^2$ is tiny, these two light quark entries provide a sensible test of the unitarity of the CKM matrix:

$$|\mathbf{V}_{ud}|^2 + |\mathbf{V}_{us}|^2 + |\mathbf{V}_{ub}|^2 = 0.9980 \pm 0.0012. \quad (122)$$

³This is completely analogous to the electromagnetic charge conservation in QED. The conservation of the electromagnetic current implies that the proton electromagnetic form factor does not get any QED or QCD correction at $q^2 = 0$ and, therefore, $Q(p) = 2Q(u) + Q(d) = |Q(e)|$. A detailed proof can be found in Ref. [51].

Table 4: Direct determinations of the CKM matrix elements V_{ij} . For $|V_{tb}|$, 95% C.L. limits are given

CKM entry	Value	Source
$ V_{ud} $	0.97377 ± 0.00027	Nuclear β decay [7]
	0.9746 ± 0.0019	$n \rightarrow p e^- \bar{\nu}_e$ [7]
	0.9728 ± 0.0030	$\pi^+ \rightarrow \pi^0 e^+ \nu_e$ [62]
	0.97378 ± 0.00027	average
$ V_{us} $	0.2234 ± 0.0024	$K \rightarrow \pi l^+ \nu_l$ [7, 34, 63]
	0.2220 ± 0.0033	τ decays [52]
	$0.2226 \begin{smallmatrix} + 0.0026 \\ - 0.0014 \end{smallmatrix}$	$K^+/\pi^+ \rightarrow \mu^+ \nu_\mu, V_{ud}$ [7, 53–55]
	0.226 ± 0.005	Hyperon decays [64–66]
	0.2230 ± 0.0015	average
$ V_{cd} $	0.213 ± 0.022	$D \rightarrow \pi l \bar{\nu}_l$ [7]
	0.230 ± 0.011	$\nu d \rightarrow c X$ [7]
	0.227 ± 0.010	average
$ V_{cs} $	0.957 ± 0.095	$D \rightarrow K l \bar{\nu}_l$ [7]
	$0.94 \begin{smallmatrix} + 0.35 \\ - 0.29 \end{smallmatrix}$	$W^+ \rightarrow c \bar{s}$ [7]
	0.974 ± 0.013	$W^+ \rightarrow \text{had.}, V_{uj}, V_{cd}, V_{cb}$ [29, 30]
$ V_{cb} $	0.0392 ± 0.0016	$B \rightarrow D^* l \bar{\nu}_l$ [7, 67]
	0.0417 ± 0.0007	$b \rightarrow c l \bar{\nu}_l$ [7, 67]
	0.0413 ± 0.0006	average
$ V_{ub} $	0.0039 ± 0.0006	$B \rightarrow \pi l \bar{\nu}_l$ [7, 67]
	0.0045 ± 0.0003	$b \rightarrow u l \bar{\nu}_l$ [7, 67]
	0.0044 ± 0.0003	average
$ V_{tb} / \sqrt{\sum_q V_{tq} ^2}$	> 0.78	$t \rightarrow b W / q W$ [68, 69]
$ V_{tb} $	$> 0.68 \quad ; \quad \leq 1$	$p\bar{p} \rightarrow tb + X$ [70]

It is important to notice that at the quoted level of uncertainty radiative corrections play a crucial role.

In the limit of very heavy quark masses, QCD has additional symmetries [56–59] which can be used to make rather precise determinations of $|V_{cb}|$, either from exclusive decays such as $B \rightarrow D^* l \bar{\nu}_l$ [60, 61] or from the inclusive analysis of $b \rightarrow c l \bar{\nu}_l$ transitions. The control of theoretical uncertainties is much more difficult for $|V_{ub}|$, $|V_{cd}|$ and $|V_{cs}|$, because the symmetry arguments associated with the light and heavy quark limits get corrected by sizeable symmetry-breaking effects.

The most precise determination of $|V_{cd}|$ is based on neutrino and antineutrino interactions. The difference of the ratio of double-muon to single-muon production by neutrino and antineutrino beams is proportional to the charm cross-section off-valence d quarks and, therefore, to $|V_{cd}|$. A direct determination of $|V_{cs}|$ can also be obtained from charm-tagged W decays at LEP2. Moreover, the ratio of the

total hadronic decay width of the W to the leptonic one provides the sum [29, 30]

$$\sum_{\substack{i=u,c \\ j=d,s,b}} |\mathbf{V}_{ij}|^2 = 1.999 \pm 0.025. \quad (123)$$

Although much less precise than Eq. (122), this result tests unitarity at the 1.25% level. From Eq. (123) one can also obtain a tighter determination of $|\mathbf{V}_{cs}|$, using the experimental knowledge on the other CKM matrix elements, i.e., $|\mathbf{V}_{ud}|^2 + |\mathbf{V}_{us}|^2 + |\mathbf{V}_{ub}|^2 + |\mathbf{V}_{cd}|^2 + |\mathbf{V}_{cb}|^2 = 1.0512 \pm 0.0058$. This gives the most accurate and final value of $|\mathbf{V}_{cs}|$ quoted in Table 4.

The measured entries of the CKM matrix show a hierarchical pattern, with the diagonal elements being very close to one, the ones connecting the two first generations having a size

$$\lambda \approx |\mathbf{V}_{us}| = 0.2230 \pm 0.0015, \quad (124)$$

the mixing between the second and third families being of order λ^2 , and the mixing between the first and third quark generations having a much smaller size of about λ^3 . It is then quite practical to use the approximate parametrization [71]:

$$\mathbf{V} = \begin{bmatrix} 1 - \frac{\lambda^2}{2} & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \frac{\lambda^2}{2} & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{bmatrix} + O(\lambda^4), \quad (125)$$

where

$$A \approx \frac{|\mathbf{V}_{cb}|}{\lambda^2} = 0.831 \pm 0.014, \quad \sqrt{\rho^2 + \eta^2} \approx \left| \frac{\mathbf{V}_{ub}}{\lambda \mathbf{V}_{cb}} \right| = 0.478 \pm 0.033. \quad (126)$$

Defining to all orders in λ [72] $s_{12} \equiv \lambda$, $s_{23} \equiv A\lambda^2$ and $s_{13} e^{-i\delta_{13}} \equiv A\lambda^3(\rho - i\eta)$, Eq. (125) just corresponds to a Taylor expansion of Eq. (117) in powers of λ .

6.2 CP violation

While parity and charge conjugation are violated by the weak interactions in a maximal way, the product of the two discrete transformations is still a good symmetry (left-handed fermions \leftrightarrow right-handed antifermions). In fact, \mathcal{CP} appears to be a symmetry of nearly all observed phenomena. However, a slight violation of the \mathcal{CP} symmetry at the level of 0.2% is observed in the neutral kaon system and more sizeable signals of \mathcal{CP} violation have been recently established at the B factories. Moreover, the huge matter–antimatter asymmetry present in our Universe is a clear manifestation of \mathcal{CP} violation and its important role in the primordial baryogenesis.

The \mathcal{CPT} theorem guarantees that the product of the three discrete transformations is an exact symmetry of any local and Lorentz-invariant quantum field theory preserving micro-causality. Therefore, a violation of \mathcal{CP} requires a corresponding violation of time reversal. Since \mathcal{T} is an antiunitary transformation, this requires the presence of relative complex phases between different interfering amplitudes.

The electroweak SM Lagrangian only contains a single complex phase δ_{13} (η). This is the sole possible source of \mathcal{CP} violation and, therefore, the SM predictions for \mathcal{CP} -violating phenomena are quite constrained. The CKM mechanism requires several necessary conditions in order to generate an observable \mathcal{CP} -violation effect. With only two fermion generations, the quark mixing mechanism cannot give rise to \mathcal{CP} violation; therefore, for \mathcal{CP} violation to occur in a particular process, all three generations are required to play an active role. In the kaon system, for instance, \mathcal{CP} -violation effects can only appear

at the one-loop level, where the top quark is present. In addition, all CKM matrix elements must be non-zero and the quarks of a given charge must be non-degenerate in mass. If any of these conditions were not satisfied, the CKM phase could be rotated away by a redefinition of the quark fields. \mathcal{CP} -violation effects are then necessarily proportional to the product of all CKM angles, and should vanish in the limit where any two (equal-charge) quark masses are taken to be equal. All these necessary conditions can be summarized in a very elegant way as a single requirement on the original quark mass matrices \mathbf{M}'_u and \mathbf{M}'_d [73]:

$$\mathcal{CP} \text{ violation} \quad \iff \quad \text{Im} \left\{ \det \left[\mathbf{M}'_u \mathbf{M}'_u{}^\dagger, \mathbf{M}'_d \mathbf{M}'_d{}^\dagger \right] \right\} \neq 0. \quad (127)$$

Without performing any detailed calculation, one can make the following general statements on the implications of the CKM mechanism of \mathcal{CP} violation:

- Owing to unitarity, for any choice of i, j, k, l (between 1 and 3),

$$\text{Im} \left[\mathbf{V}_{ij} \mathbf{V}_{ik}^* \mathbf{V}_{lk} \mathbf{V}_{lj}^* \right] = \mathcal{J} \sum_{m,n=1}^3 \epsilon_{ilm} \epsilon_{jkn}, \quad (128)$$

$$\mathcal{J} = c_{12} c_{23} c_{13}^2 s_{12} s_{23} s_{13} \sin \delta_{13} \approx A^2 \lambda^6 \eta < 10^{-4}. \quad (129)$$

Any \mathcal{CP} -violation observable involves the product \mathcal{J} [73]. Thus, violations of the \mathcal{CP} symmetry are necessarily small.

- In order to have sizeable \mathcal{CP} -violating asymmetries $\mathcal{A} \equiv (\Gamma - \bar{\Gamma})/(\Gamma + \bar{\Gamma})$, one should look for very suppressed decays, where the decay widths already involve small CKM matrix elements.
- In the SM, \mathcal{CP} violation is a low-energy phenomenon, in the sense that any effect should disappear when the quark mass difference $m_c - m_u$ becomes negligible.
- B decays are the optimal place for \mathcal{CP} -violation signals to show up. They involve small CKM matrix elements and are the lowest-mass processes where the three quark generations play a direct (tree-level) role.

The SM mechanism of \mathcal{CP} violation is based on the unitarity of the CKM matrix. Testing the constraints implied by unitarity is then a way to test the source of \mathcal{CP} violation. The unitarity tests in Eqs. (122) and (123) involve only the moduli of the CKM parameters, while \mathcal{CP} violation has to do with their phases. More interesting are the off-diagonal unitarity conditions:

$$\mathbf{V}_{ud}^* \mathbf{V}_{us} + \mathbf{V}_{cd}^* \mathbf{V}_{cs} + \mathbf{V}_{td}^* \mathbf{V}_{ts} = 0, \quad (130)$$

$$\mathbf{V}_{us}^* \mathbf{V}_{ub} + \mathbf{V}_{cs}^* \mathbf{V}_{cb} + \mathbf{V}_{ts}^* \mathbf{V}_{tb} = 0, \quad (131)$$

$$\mathbf{V}_{ub}^* \mathbf{V}_{ud} + \mathbf{V}_{cb}^* \mathbf{V}_{cd} + \mathbf{V}_{tb}^* \mathbf{V}_{td} = 0. \quad (132)$$

These relations can be visualized by triangles in a complex plane which, owing to Eq. (128), have the same area $|\mathcal{J}|/2$. In the absence of \mathcal{CP} violation, these triangles would degenerate into segments along the real axis.

In the first two triangles, one side is much shorter than the other two (the Cabibbo suppression factors of the three sides are λ , λ and λ^5 in the first triangle, and λ^4 , λ^2 and λ^2 in the second one). This is why \mathcal{CP} effects are so small for K mesons (first triangle), and why certain asymmetries in B_s decays are predicted to be tiny (second triangle). The third triangle looks more interesting, since the three sides have a similar size of about λ^3 . They are small, which means that the relevant b -decay branching ratios are small, but once enough B mesons have been produced, the \mathcal{CP} -violation asymmetries are sizeable. The present experimental constraints on this triangle are shown in Fig. 31, where it has been scaled by dividing its sides by $\mathbf{V}_{cb}^* \mathbf{V}_{cd}$. This aligns one side of the triangle along the real axis and makes its length equal to 1; the coordinates of the three vertices are then $(0, 0)$, $(1, 0)$ and $(\bar{\rho}, \bar{\eta}) \equiv (1 - \lambda^2/2)(\rho, \eta)$.

Fig. 31: Experimental constraints on the SM unitarity triangle [77]

Fig. 32: B^0 - \bar{B}^0 mixing diagrams. Owing to the unitarity of the CKM matrix, the mixing vanishes for equal up-type quark masses (GIM mechanism). The mixing amplitude is then proportional to the mass (squared) splittings between the u , c and t quarks, and is completely dominated by the top contribution.

One side of the unitarity triangle has already been determined in Eq. (126) from the ratio $|V_{ub}/V_{cb}|$. The other side can be obtained from the measured mixing between the B_d^0 and \bar{B}_d^0 mesons (Fig. 32), $\Delta M_d = 0.507 \pm 0.004 \text{ ps}^{-1}$ [67], which fixes $|V_{tb}|$. Additional information has been provided by the recent observation of B_s^0 - \bar{B}_s^0 oscillations at CDF, implying $\Delta M_s = 17.77 \pm 0.12 \text{ ps}^{-1}$ [74]. From the experimental ratio $\Delta M_d/\Delta M_s = 0.0286 \pm 0.0003$, one obtains $|V_{td}|/|V_{ts}|$. A more direct constraint on the parameter η is given by the observed \mathcal{CP} violation in $K^0 \rightarrow 2\pi$ decays. The measured value of $|\varepsilon_K| = (2.232 \pm 0.007) \cdot 10^{-3}$ [7] determines the parabolic region shown in Fig. 31.

B^0 decays into \mathcal{CP} self-conjugate final states provide independent ways to determine the angles of the unitarity triangle [75, 76]. The B^0 (or \bar{B}^0) can decay directly to the given final state f , or do it after the meson has been changed to its antiparticle via the mixing process. \mathcal{CP} -violating effects can then result from the interference of these two contributions. The time-dependent \mathcal{CP} -violating rate asymmetries contain direct information on the CKM parameters. The gold-plated decay mode is $B_d^0 \rightarrow J/\psi K_S$, which gives a clean measurement of $\beta \equiv -\arg(\mathbf{V}_{cd}\mathbf{V}_{cb}^*/\mathbf{V}_{td}\mathbf{V}_{tb}^*)$, without strong-interaction uncertainties. Including the information obtained from other $b \rightarrow c\bar{c}s$ decays, one gets [67]:

$$\sin 2\beta = 0.68 \pm 0.03. \quad (133)$$

Many additional tests of the CKM matrix from different B decay modes are being pursued at the B factories. Determinations of the other two angles of the unitarity triangle, $\alpha \equiv -\arg(\mathbf{V}_{td}\mathbf{V}_{tb}^*/\mathbf{V}_{ud}\mathbf{V}_{ub}^*)$ and $\gamma \equiv -\arg(\mathbf{V}_{ud}\mathbf{V}_{ub}^*/\mathbf{V}_{cd}\mathbf{V}_{cb}^*)$, have already been obtained [67, 78], and are included in the global fit shown in Fig. 31 [77, 79]. Complementary and very valuable information could be also obtained from the kaon decay modes $K^\pm \rightarrow \pi^\pm \nu \bar{\nu}$, $K_L \rightarrow \pi^0 \nu \bar{\nu}$ and $K_L \rightarrow \pi^0 e^+ e^-$ [80].

Fig. 33: Measured fluxes of 8B solar neutrinos of ν_μ or ν_τ type ($\phi_{\mu,\tau}$) versus the flux of ν_e (ϕ_e) [83]

6.3 Lepton mixing

The so-called ‘solar neutrino problem’ has been a long-standing question since the very first chlorine experiment at the Homestake mine [81]. The flux of solar ν_e neutrinos reaching the Earth has been measured by several experiments to be significantly below the standard solar model prediction [82]. More recently, the Sudbury Neutrino Observatory has provided strong evidence that neutrinos do change flavour as they propagate from the core of the Sun [83], independently of solar model flux predictions. SNO is able to detect neutrinos through three different reactions: the charged-current process $\nu_e d \rightarrow e^- pp$ which is only sensitive to ν_e , the neutral current transition $\nu_x d \rightarrow \nu_x pn$ which has equal probability for all active neutrino flavours, and the elastic scattering $\nu_x e^- \rightarrow \nu_x e^-$ which is also sensitive to ν_μ and ν_τ , although the corresponding cross-section is a factor 6.48 smaller than the ν_e one. The measured neutrino fluxes, shown in Fig. 33, demonstrate the existence of a non- ν_e component in the solar neutrino flux at the 5.3σ level. The SNO results are in good agreement with the Super-Kamiokande solar measurements [84] and have been further reinforced with the more recent KamLAND data, showing that $\bar{\nu}_e$ from nuclear reactors disappear over distances of about 180 km [85].

Another evidence of oscillations has been obtained from atmospheric neutrinos. The known discrepancy between the experimental observations and the predicted ratio of muon to electron neutrinos has become much stronger with the high precision and large statistics of Super-Kamiokande [86]. The atmospheric anomaly appears to originate in a reduction of the ν_μ flux, and the data strongly favours the $\nu_\mu \rightarrow \nu_\tau$ hypothesis. This result has been confirmed by K2K [87] and MINOS [88], observing the disappearance of accelerator ν_μ 's at distances of 250 and 735 km, respectively. Super-Kamiokande has recently reported statistical evidence of ν_τ appearance at the 2.4σ level [86]. The direct detection of the produced ν_τ is the main goal of the ongoing CERN to Gran Sasso neutrino programme.

Thus, we now have clear experimental evidence that neutrinos are massive particles and there is mixing in the lepton sector. Figures 34 and 35 show the present information on neutrino oscillations, from solar, atmospheric, accelerator, and reactor neutrino data. A global analysis, combining the full set of data, leads to the following preferred ranges for the oscillation parameters [7]:

$$\Delta m_{21}^2 = (8.0^{+0.4}_{-0.3}) \cdot 10^{-5} \text{ eV}^2, \quad 1.9 \cdot 10^{-3} < |\Delta m_{32}^2| / \text{eV}^2 < 3.0 \cdot 10^{-3}, \quad (134)$$

$$\sin^2(2\theta_{12}) = 0.86^{+0.03}_{-0.04}, \quad \sin^2(2\theta_{23}) > 0.92, \quad \sin^2(2\theta_{13}) < 0.19, \quad (135)$$

where $\Delta m_{ij}^2 \equiv m_i^2 - m_j^2$ are the mass squared differences between the neutrino mass eigenstates $\nu_{i,j}$ and θ_{ij} the corresponding mixing angles in the standard three-flavour parametrization [7]. The ranges indicate 90% C.L. bounds. In the limit $\theta_{13} = 0$, solar and atmospheric neutrino oscillations decouple

because $\Delta m_{\odot}^2 \ll \Delta m_{\text{atm}}^2$. Thus, Δm_{21}^2 , θ_{12} and θ_{13} are constrained by solar data, while atmospheric experiments constrain Δm_{32}^2 , θ_{23} and θ_{13} . The angle θ_{13} is strongly constrained by the CHOOZ reactor experiment [89]. New planned reactor experiments T2K and NO ν A are expected to achieve sensitivities around $\sin^2(2\theta_{13}) \sim 0.01$.

Fig. 34: Allowed regions for 2ν oscillations for the combination of solar (ν_e) and KamLAND ($\bar{\nu}_e$) data, assuming \mathcal{CPT} symmetry [83]

Fig. 35: MINOS allowed regions for ν_μ disappearance oscillations, compared with K2K and Super-Kamiokande results [88]

Non-zero neutrino masses constitute a clear indication of new physics beyond the SM. Right-handed neutrinos are an obvious possibility to incorporate Dirac neutrino masses. However, the ν_{iR} fields would be $SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$ singlets, without any SM interaction. If such objects do exist, it would seem natural to expect that they be able to communicate with the rest of the world through some still unknown dynamics. Moreover, the SM gauge symmetry would allow for a right-handed Majorana neutrino mass term,

$$\mathcal{L}_M = -\frac{1}{2} \overline{\nu_{iR}^c} M_{ij} \nu_{jR} + \text{h.c.}, \quad (136)$$

where $\nu_{iR}^c \equiv \mathcal{C} \bar{\nu}_{iR}^T$ denotes the charge-conjugated field. The Majorana mass matrix M_{ij} could have an arbitrary size, because it is not related to the ordinary Higgs mechanism. Since both fields ν_{iR} and $\overline{\nu_{iR}^c}$ absorb ν and create $\bar{\nu}$, the Majorana mass term mixes neutrinos and anti-neutrinos, violating lepton number by two units. Clearly, new physics is called for.

Adopting a more general effective field theory language, without any assumption about the existence of right-handed neutrinos or any other new particles, one can write the most general $SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$ invariant Lagrangian in terms of the known low-energy fields (left-handed neutrinos only). The SM is the unique answer with dimension four. The first contributions from new physics appear through dimension-5 operators, and have also a unique form which violates lepton number by two units [90]:

$$\Delta\mathcal{L} = -\frac{c_{ij}}{\Lambda} \bar{L}_i \tilde{\phi} \tilde{\phi}^t L_j^c + \text{h.c.}, \quad (137)$$

where L_i denotes the i -flavoured $SU(2)_L$ lepton doublet, $\tilde{\phi} \equiv i\tau_2 \phi^*$ and $L_i^c \equiv \mathcal{C} \bar{L}_i^T$. Similar operators with quark fields are forbidden, owing to their different hypercharges, while higher-dimension operators would be suppressed by higher powers of the new-physics scale Λ . After SSB, $\langle \phi^{(0)} \rangle = v/\sqrt{2}$, $\Delta\mathcal{L}$ generates a Majorana mass term for the left-handed neutrinos, with⁴ $M_{ij} = c_{ij}v^2/\Lambda$. Thus, Majorana neutrino masses should be expected on general symmetry grounds. Taking $m_\nu \gtrsim 0.05$ eV, as suggested

⁴This relation generalizes the well-known see-saw mechanism ($m_{\nu_L} \sim m^2/\Lambda$) [91,92].

Table 5: Best published limits (90% C.L.) on lepton-flavour-violating decays [7, 49, 50]

$\text{Br}(\mu^- \rightarrow e^- \gamma) < 1.2 \cdot 10^{-11}$	$\text{Br}(\mu^- \rightarrow e^- 2\gamma) < 7.2 \cdot 10^{-11}$	$\text{Br}(\mu^- \rightarrow e^- e^- e^+) < 1.0 \cdot 10^{-12}$
$\text{Br}(\tau^- \rightarrow \mu^- \gamma) < 4.5 \cdot 10^{-8}$	$\text{Br}(\tau^- \rightarrow e^- \gamma) < 1.1 \cdot 10^{-7}$	$\text{Br}(\tau^- \rightarrow e^- e^- \mu^+) < 1.1 \cdot 10^{-7}$
$\text{Br}(\tau^- \rightarrow e^- K_S) < 5.6 \cdot 10^{-8}$	$\text{Br}(\tau^- \rightarrow \mu^- K_S) < 4.9 \cdot 10^{-8}$	$\text{Br}(\tau^- \rightarrow \mu^+ \pi^- \pi^-) < 0.7 \cdot 10^{-7}$
$\text{Br}(\tau^- \rightarrow \Lambda \pi^-) < 7.2 \cdot 10^{-8}$	$\text{Br}(\tau^- \rightarrow e^- \pi^0) < 1.4 \cdot 10^{-7}$	$\text{Br}(\tau^- \rightarrow e^- \pi^+ \pi^-) < 1.2 \cdot 10^{-7}$
$\text{Br}(\tau^- \rightarrow \mu^- \pi^0) < 1.1 \cdot 10^{-7}$	$\text{Br}(\tau^- \rightarrow \mu^- \eta) < 1.3 \cdot 10^{-7}$	$\text{Br}(\tau^- \rightarrow \mu^- e^+ \mu^-) < 1.3 \cdot 10^{-7}$

by atmospheric neutrino data, one gets $\Lambda/c_{ij} \lesssim 10^{15}$ GeV, amazingly close to the expected scale of Grand Unification.

With non-zero neutrino masses, the leptonic charged-current interactions involve a flavour mixing matrix \mathbf{V}_L . The data on neutrino oscillations imply that all elements of \mathbf{V}_L are large, except for $(\mathbf{V}_L)_{e3} < 0.18$; therefore the mixing among leptons appears to be very different from the one in the quark sector. The number of relevant phases characterizing the matrix \mathbf{V}_L depends on the Dirac or Majorana nature of neutrinos, because if one rotates a Majorana neutrino by a phase, this phase will appear in its mass term which will no longer be real. With only three Majorana (Dirac) neutrinos, the 3×3 matrix \mathbf{V}_L involves six (four) independent parameters: three mixing angles and three (one) phases.

The smallness of neutrino masses implies a strong suppression of neutrinoless lepton-flavour-violating processes, which can be avoided in models with other sources of lepton-flavour violation, not related to m_{ν_i} . Table 5 shows the best published limits on lepton-flavour-violating decays. The B Factories are pushing the experimental limits on neutrinoless τ decays beyond the 10^{-7} level, increasing in a drastic way the sensitivity to new physics scales. Future experiments could further push some limits to the 10^{-9} level, allowing one to explore interesting and totally unknown phenomena. Complementary information will be provided by the MEG experiment, which will search for $\mu^+ \rightarrow e^+ \gamma$ events with a sensitivity of 10^{-13} [93]. There are also ongoing projects at J-PARC aiming to study $\mu \rightarrow e$ conversions in muonic atoms, at the 10^{-18} level.

At present, we still ignore whether neutrinos are Dirac or Majorana fermions. Another important question to be addressed in the future concerns the possibility of leptonic CP violation and its relevance for explaining the baryon asymmetry of our Universe through leptogenesis.

7 Summary

The SM provides a beautiful theoretical framework which is able to accommodate all our present knowledge on electroweak and strong interactions. It is able to explain any single experimental fact and, in some cases, it has successfully passed very precise tests at the 0.1% to 1% level. In spite of this impressive phenomenological success, the SM leaves too many unanswered questions to be considered as a complete description of the fundamental forces. We do not understand yet why fermions are replicated in three (and only three) nearly identical copies. Why the pattern of masses and mixings is what it is. Are the masses the only difference among the three families? What is the origin of the SM flavour structure? Which dynamics is responsible for the observed \mathcal{CP} violation?

In the gauge and scalar sectors, the SM Lagrangian contains only four parameters: g , g' , μ^2 , and h . We can trade them by α , M_Z , G_F , and M_H ; this has the advantage of using the three most precise experimental determinations to fix the interaction. In any case, one describes a lot of physics with only four inputs. In the fermionic flavour sector, however, the situation is very different. With $N_G = 3$, we have 13 additional free parameters in the minimal SM: 9 fermion masses, 3 quark mixing angles and 1 phase. Taking into account non-zero neutrino masses, we have three more mass parameters plus the leptonic mixings: three angles and one phase (three phases) for Dirac (or Majorana) neutrinos.

Clearly, this is not very satisfactory. The source of this proliferation of parameters is the set of unknown Yukawa couplings in Eq. (109). The origin of masses and mixings, together with the reason for the existing family replication, constitute at present the main open problem in electroweak physics. The problem of fermion mass generation is deeply related to the mechanism responsible for the electroweak SSB. Thus, the origin of these parameters lies in the most obscure part of the SM Lagrangian: the scalar sector. The dynamics of flavour appears to be *terra incognita* which deserves a careful investigation.

The SM incorporates a mechanism to generate \mathcal{CP} violation, through the single phase naturally occurring in the CKM matrix. Although the present laboratory experiments are well described, this mechanism is unable to explain the matter–antimatter asymmetry of our Universe. A fundamental explanation of the origin of \mathcal{CP} -violating phenomena is still lacking.

The first hints of new physics beyond the SM have emerged recently, with convincing evidence of neutrino oscillations showing that $\nu_e \rightarrow \nu_{\mu,\tau}$ and $\nu_{\mu} \rightarrow \nu_{\tau}$ transitions do occur. The existence of lepton-flavour violation opens a very interesting window to unknown phenomena.

The Higgs particle is the main missing block of the SM framework. The successful tests of the SM quantum corrections with precision electroweak data confirm the assumed pattern of SSB, but do not prove the validity of the minimal Higgs mechanism embedded in the SM. The present experimental bounds (108) put the Higgs hunting within the reach of the new generation of detectors. The LHC should find out whether such scalar field indeed exists, either confirming the SM Higgs mechanism or discovering completely new phenomena.

Many interesting experimental signals are expected to be seen in the near future. New experiments will probe the SM to a much deeper level of sensitivity and will explore the frontier of its possible extensions. Large surprises may well be expected, probably establishing the existence of new physics beyond the SM and offering clues to the problems of mass generation, fermion mixing, and family replication.

Acknowledgements

I want to thank the organizers for the charming atmosphere of this school and all the students for their many interesting questions and comments. This work has been supported by the EU MRTN-CT-2006-035482 (FLAVIANet), MEC (Spain, FPA2004-00996), and Generalitat Valenciana (GVACOMP2007-156).

Appendices

A Basic inputs from quantum field theory

A.1 Wave equations

The classical Hamiltonian of a non-relativistic free particle is given by $H = \vec{p}^2/(2m)$. In quantum mechanics, energy and momentum correspond to operators acting on the particle wave function. The substitutions $H = i\hbar \frac{\partial}{\partial t}$ and $\vec{p} = -i\hbar \vec{\nabla}$ lead then to the Schrödinger equation:

$$i\hbar \frac{\partial}{\partial t} \psi(\vec{x}, t) = -\frac{\hbar^2}{2m} \vec{\nabla}^2 \psi(\vec{x}, t). \quad (\text{A.1})$$

We can write the energy and momentum operators in a relativistic covariant way as $p^\mu = i\partial^\mu \equiv i\frac{\partial}{\partial x_\mu}$, where we have adopted the usual natural units convention $\hbar = c = 1$. The relation $E^2 = \vec{p}^2 + m^2$ determines the Klein–Gordon equation for a relativistic free particle:

$$(\square + m^2) \phi(x) = 0, \quad \square \equiv \partial^\mu \partial_\mu = \frac{\partial^2}{\partial t^2} - \vec{\nabla}^2. \quad (\text{A.2})$$

The Klein–Gordon equation is quadratic on the time derivative because relativity puts the space and time coordinates on an equal footing. Let us investigate whether an equation linear in derivatives could exist. Relativistic covariance and dimensional analysis restrict its possible form to

$$(i\gamma^\mu \partial_\mu - m) \psi(x) = 0. \quad (\text{A.3})$$

Since the r.h.s. is identically zero, we can fix the coefficient of the mass term to be -1 ; this just determines the normalization of the four coefficients γ^μ . Notice that γ^μ should transform as a Lorentz four-vector. The solutions of Eq. (A.3) should also satisfy the Klein–Gordon relation of Eq. (A.2). Applying an appropriate differential operator to Eq. (A.3), one can easily obtain the required quadratic equation:

$$-(i\gamma^\nu \partial_\nu + m)(i\gamma^\mu \partial_\mu - m) \psi(x) = 0 \equiv (\square + m^2) \psi(x). \quad (\text{A.4})$$

Terms linear in derivatives cancel identically, while the term with two derivatives reproduces the operator $\square \equiv \partial^\mu \partial_\mu$ provided the coefficients γ^μ satisfy the algebraic relation

$$\{\gamma^\mu, \gamma^\nu\} \equiv \gamma^\mu \gamma^\nu + \gamma^\nu \gamma^\mu = 2g^{\mu\nu}, \quad (\text{A.5})$$

which defines the so-called Dirac algebra. Eq. (A.3) is known as the Dirac equation.

Obviously the components of the four-vector γ^μ cannot simply be numbers. The three 2×2 Pauli matrices satisfy $\{\sigma^i, \sigma^j\} = 2\delta^{ij}$, which is very close to the relation (A.5). The lowest-dimensional solution to the Dirac algebra is obtained with $D = 4$ matrices. An explicit representation is given by:

$$\gamma^0 = \begin{pmatrix} I_2 & 0 \\ 0 & -I_2 \end{pmatrix}, \quad \gamma^i = \begin{pmatrix} 0 & \sigma^i \\ -\sigma^i & 0 \end{pmatrix}. \quad (\text{A.6})$$

Thus, the wave function $\psi(x)$ is a column vector with four components in the Dirac space. The presence of the Pauli matrices strongly suggests that it contains two components of spin $\frac{1}{2}$. A proper physical analysis of its solutions shows that the Dirac equation describes simultaneously a fermion of spin $\frac{1}{2}$ and its own antiparticle [94].

It is useful to define the following combinations of gamma matrices:

$$\sigma^{\mu\nu} \equiv \frac{i}{2} [\gamma^\mu, \gamma^\nu], \quad \gamma_5 \equiv \gamma^5 \equiv i\gamma^0 \gamma^1 \gamma^2 \gamma^3 = -\frac{i}{4!} \epsilon_{\mu\nu\rho\sigma} \gamma^\mu \gamma^\nu \gamma^\rho \gamma^\sigma. \quad (\text{A.7})$$

In the explicit representation (A.6),

$$\sigma^{ij} = \epsilon^{ijk} \begin{pmatrix} \sigma^k & 0 \\ 0 & \sigma^k \end{pmatrix}, \quad \sigma^{0i} = i \begin{pmatrix} 0 & \sigma^i \\ \sigma^i & 0 \end{pmatrix}, \quad \gamma_5 = \begin{pmatrix} 0 & I_2 \\ I_2 & 0 \end{pmatrix}. \quad (\text{A.8})$$

The matrix σ^{ij} is then related to the spin operator. Some important properties are

$$\gamma^0 \gamma^\mu \gamma^0 = \gamma^{\mu\dagger}, \quad \gamma^0 \gamma_5 \gamma^0 = -\gamma_5^\dagger = -\gamma_5, \quad \{\gamma_5, \gamma^\mu\} = 0, \quad (\gamma_5)^2 = I_4. \quad (\text{A.9})$$

Specially relevant for weak interactions are the chirality projectors ($P_L + P_R = 1$)

$$P_L \equiv \frac{1 - \gamma_5}{2}, \quad P_R \equiv \frac{1 + \gamma_5}{2}, \quad P_R^2 = P_R, \quad P_L^2 = P_L, \quad P_L P_R = P_R P_L = 0, \quad (\text{A.10})$$

which allow us to decompose the Dirac spinor in its left-handed and right-handed chirality parts:

$$\psi(x) = [P_L + P_R] \psi(x) \equiv \psi_L(x) + \psi_R(x). \quad (\text{A.11})$$

In the massless limit, the chiralities correspond to the fermion helicities.

A.2 Lagrangian formalism

The Lagrangian formulation of a physical system provides a compact dynamical description and makes it easier to discuss the underlying symmetries. Like in classical mechanics, the dynamics is encoded in the action

$$S = \int d^4x \mathcal{L}[\phi_i(x), \partial_\mu \phi_i(x)]. \quad (\text{A.12})$$

The integral over the four space–time coordinates preserves relativistic invariance. The Lagrangian density \mathcal{L} is a Lorentz-invariant functional of the fields $\phi_i(x)$ and their derivatives. The space integral $L = \int d^3x \mathcal{L}$ would correspond to the usual non-relativistic Lagrangian.

The principle of stationary action requires the variation δS of the action to be zero under small fluctuations $\delta \phi_i$ of the fields. Assuming that the variations $\delta \phi_i$ are differentiable and vanish outside some bounded region of space–time (which allows an integration by parts), the condition $\delta S = 0$ determines the Euler–Lagrange equations of motion for the fields:

$$\frac{\partial \mathcal{L}}{\partial \phi_i} - \partial^\mu \left(\frac{\partial \mathcal{L}}{\partial (\partial^\mu \phi_i)} \right) = 0. \quad (\text{A.13})$$

One can easily find appropriate Lagrangians to generate the Klein–Gordon and Dirac equations. They should be quadratic on the fields and Lorentz invariant, which determines their possible form up to irrelevant total derivatives. The Lagrangian

$$\mathcal{L} = \partial^\mu \phi^* \partial_\mu \phi - m^2 \phi^* \phi \quad (\text{A.14})$$

describes a complex scalar field without interactions. Both the field $\phi(x)$ and its complex conjugate $\phi^*(x)$ satisfy the Klein–Gordon equation; thus, $\phi(x)$ describes a particle of mass m without spin and its antiparticle. Particles which are their own antiparticles (i.e., with no internal charges) have only one degree of freedom and are described through a real scalar field. The appropriate Klein–Gordon Lagrangian is then

$$\mathcal{L} = \frac{1}{2} \partial^\mu \phi \partial_\mu \phi - \frac{1}{2} m^2 \phi^2. \quad (\text{A.15})$$

The Dirac equation can be derived from the Lagrangian density

$$\mathcal{L} = \bar{\psi} (i \gamma^\mu \partial_\mu - m) \psi. \quad (\text{A.16})$$

The adjoint spinor $\bar{\psi}(x) = \psi^\dagger(x) \gamma^0$ closes the Dirac indices. The matrix γ^0 is included to guarantee the proper behaviour under Lorentz transformations: $\bar{\psi}\psi$ is a Lorentz scalar, while $\bar{\psi}\gamma^\mu\psi$ transforms as a four-vector [94]. Therefore, \mathcal{L} is Lorentz invariant as it should be.

Using the decomposition (A.11) of the Dirac field in its two chiral components, the fermionic Lagrangian adopts the form:

$$\mathcal{L} = \bar{\psi}_L i \gamma^\mu \partial_\mu \psi_L + \bar{\psi}_R i \gamma^\mu \partial_\mu \psi_R - m (\bar{\psi}_L \psi_R + \bar{\psi}_R \psi_L). \quad (\text{A.17})$$

Thus, the two chiralities decouple if the fermion is massless.

A.3 Symmetries and conservation laws

Let us assume that the Lagrangian of a physical system is invariant under some set of continuous transformations

$$\phi_i(x) \rightarrow \phi'_i(x) = \phi_i(x) + \epsilon \delta_\epsilon \phi_i(x) + O(\epsilon^2), \quad (\text{A.18})$$

i.e., $\mathcal{L}[\phi_i(x), \partial_\mu \phi_i(x)] = \mathcal{L}[\phi'_i(x), \partial_\mu \phi'_i(x)]$. One finds then that

$$\delta_\epsilon \mathcal{L} = 0 = \sum_i \left\{ \left[\frac{\partial \mathcal{L}}{\partial \phi_i} - \partial^\mu \left(\frac{\partial \mathcal{L}}{\partial (\partial^\mu \phi_i)} \right) \right] \delta_\epsilon \phi_i + \partial^\mu \left[\frac{\partial \mathcal{L}}{\partial (\partial^\mu \phi_i)} \delta_\epsilon \phi_i \right] \right\}. \quad (\text{A.19})$$

If the fields satisfy the Euler–Lagrange equations of motion (A.13), the first term is identically zero; therefore the system has a conserved current:

$$J_\mu \equiv \sum_i \frac{\partial \mathcal{L}}{\partial (\partial^\mu \phi_i)} \delta_\epsilon \phi_i, \quad \partial^\mu J_\mu = 0. \quad (\text{A.20})$$

This allows us to define a conserved charge

$$Q \equiv \int d^3x J^0. \quad (\text{A.21})$$

The condition $\partial^\mu J_\mu = 0$ guarantees that $\frac{dQ}{dt} = 0$, i.e., that Q is a constant of motion.

This result, known as Noether’s theorem, can be easily extended to general transformations involving also the space–time coordinates. For every continuous symmetry transformation which leaves the Lagrangian invariant, there is a corresponding divergenceless Noether’s current and, therefore, a conserved charge. The selection rules observed in Nature, where there exist several conserved quantities (energy, momentum, angular momentum, electric charge, etc.), correspond to dynamical symmetries of the Lagrangian.

A.4 Classical electrodynamics

The well-known Maxwell equations,

$$\vec{\nabla} \cdot \vec{B} = 0, \quad \vec{\nabla} \times \vec{E} + \frac{\partial \vec{B}}{\partial t} = 0, \quad (\text{A.22})$$

$$\vec{\nabla} \cdot \vec{E} = \rho, \quad \vec{\nabla} \times \vec{B} - \frac{\partial \vec{E}}{\partial t} = \vec{J}, \quad (\text{A.23})$$

summarize a large amount of experimental and theoretical work and provide a unified description of the electric and magnetic forces. The first two equations in (A.22) are easily solved, writing the electromagnetic fields in terms of potentials:

$$\vec{E} = -\vec{\nabla}V - \frac{\partial \vec{A}}{\partial t}, \quad \vec{B} = \vec{\nabla} \times \vec{A}. \quad (\text{A.24})$$

It is very useful to rewrite these equations in a Lorentz covariant notation. The charge density ρ and the electromagnetic current \vec{J} transform as a four-vector $J^\mu \equiv (\rho, \vec{J})$. The same is true for the potentials which combine into $A^\mu \equiv (V, \vec{A})$. The relations (A.24) between the potentials and the fields then take a very simple form, which defines the field strength tensor:

$$F^{\mu\nu} \equiv \partial^\mu A^\nu - \partial^\nu A^\mu = \begin{pmatrix} 0 & -E_1 & -E_2 & -E_3 \\ E_1 & 0 & -B_3 & B_2 \\ E_2 & B_3 & 0 & -B_1 \\ E_3 & -B_2 & B_1 & 0 \end{pmatrix}, \quad \tilde{F}^{\mu\nu} \equiv \frac{1}{2} \epsilon^{\mu\nu\rho\sigma} F_{\rho\sigma}. \quad (\text{A.25})$$

In terms of the tensor $F^{\mu\nu}$, the covariant form of the Maxwell equations turns out to be very transparent:

$$\partial_\mu \tilde{F}^{\mu\nu} = 0, \quad \partial_\mu F^{\mu\nu} = J^\nu. \quad (\text{A.26})$$

The electromagnetic dynamics is clearly a relativistic phenomenon, but Lorentz invariance was not very explicit in the original formulation of Eqs. (A.22) and (A.23). Once a covariant formulation is adopted, the equations become much simpler. The conservation of the electromagnetic current appears now as a natural compatibility condition:

$$\partial_\nu J^\nu = \partial_\nu \partial_\mu F^{\mu\nu} = 0. \quad (\text{A.27})$$

In terms of potentials, $\partial_\mu \tilde{F}^{\mu\nu}$ is identically zero while $\partial_\mu F^{\mu\nu} = J^\nu$ adopts the form

$$\square A^\nu - \partial^\nu (\partial_\mu A^\mu) = J^\nu. \quad (\text{A.28})$$

The same dynamics can be described by many different electromagnetic four-potentials, which give the same field strength tensor $F^{\mu\nu}$. Thus, the Maxwell equations are invariant under gauge transformations:

$$A^\mu \longrightarrow A'^\mu = A^\mu + \partial^\mu \Lambda. \quad (\text{A.29})$$

Taking the *Lorentz gauge* $\partial_\mu A^\mu = 0$, Eq. (A.28) simplifies to

$$\square A^\nu = J^\nu. \quad (\text{A.30})$$

In the absence of an external current, i.e., with $J^\mu = 0$, the four components of A^μ satisfy then a Klein–Gordon equation with $m = 0$. The photon is therefore a massless particle.

The Lorentz condition $\partial_\mu A^\mu = 0$ still allows for a residual gauge invariance under transformations of the type (A.29), with the restriction $\square \Lambda = 0$. Thus, we can impose a second constraint on the electromagnetic field A^μ , without changing $F^{\mu\nu}$. Since A^μ contains four fields ($\mu = 0, 1, 2, 3$) and there are two arbitrary constraints, the number of physical degrees of freedom is just two. Therefore, the photon has two different physical polarizations.

B SU(N) algebra

$SU(N)$ is the group of $N \times N$ unitary matrices, $UU^\dagger = U^\dagger U = 1$, with $\det U = 1$. Any $SU(N)$ matrix can be written in the form

$$U = \exp \{i T^a \theta_a\}, \quad a = 1, 2, \dots, N^2 - 1, \quad (\text{B.1})$$

with $T^a = \lambda^a/2$ Hermitian, traceless matrices. Their commutation relations

$$[T^a, T^b] = i f^{abc} T^c \quad (\text{B.2})$$

define the $SU(N)$ algebra. The $N \times N$ matrices $\lambda^a/2$ generate the fundamental representation of the $SU(N)$ algebra. The basis of generators $\lambda^a/2$ can be chosen so that the structure constants f^{abc} are real and totally antisymmetric.

For $N = 2$, λ^a are the usual Pauli matrices,

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad (\text{B.3})$$

which satisfy the commutation relation

$$[\sigma_i, \sigma_j] = 2i \epsilon_{ijk} \sigma_k. \quad (\text{B.4})$$

Other useful properties are: $\{\sigma_i, \sigma_j\} = 2\delta_{ij}$ and $\text{Tr}(\sigma_i \sigma_j) = 2\delta_{ij}$.

For $N = 3$, the fundamental representation corresponds to the eight Gell-Mann matrices:

$$\lambda^1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \lambda^2 = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \lambda^3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \lambda^4 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad (\text{B.5})$$

$$\lambda^5 = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix}, \quad \lambda^6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad \lambda^7 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix}, \quad \lambda^8 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}.$$

They satisfy the anticommutation relation

$$\{\lambda^a, \lambda^b\} = \frac{4}{N} \delta^{ab} I_N + 2d^{abc} \lambda^c, \quad (\text{B.6})$$

where I_N denotes the N -dimensional unit matrix and the constants d^{abc} are totally symmetric in the three indices.

For $SU(3)$, the only non-zero (up to permutations) f^{abc} and d^{abc} constants are

$$\frac{1}{2} f^{123} = f^{147} = -f^{156} = f^{246} = f^{257} = f^{345} = -f^{367} = \frac{1}{\sqrt{3}} f^{458} = \frac{1}{\sqrt{3}} f^{678} = \frac{1}{2}, \quad (\text{B.7})$$

$$d^{146} = d^{157} = -d^{247} = d^{256} = d^{344} = d^{355} = -d^{366} = -d^{377} = \frac{1}{2}, \quad (\text{B.8})$$

$$d^{118} = d^{228} = d^{338} = -2d^{448} = -2d^{558} = -2d^{668} = -2d^{778} = -d^{888} = \frac{1}{\sqrt{3}}.$$

The adjoint representation of the $SU(N)$ group is given by the $(N^2 - 1) \times (N^2 - 1)$ matrices $(T_A^a)_{bc} \equiv -if^{abc}$, which satisfy the commutation relations (B.2). The following equalities

$$\begin{aligned} \text{Tr}(\lambda^a \lambda^b) &= 4T_F \delta_{ab}, & T_F &= \frac{1}{2}, \\ (\lambda^a \lambda^a)_{\alpha\beta} &= 4C_F \delta_{\alpha\beta}, & C_F &= \frac{N^2 - 1}{2N}, \end{aligned} \quad (\text{B.9})$$

$$\text{Tr}(T_A^a T_A^b) = f^{acd} f^{bcd} = C_A \delta_{ab}, \quad C_A = N,$$

define the $SU(N)$ invariants T_F , C_F and C_A . Other useful properties are

$$\begin{aligned} (\lambda^a)_{\alpha\beta} (\lambda^a)_{\gamma\delta} &= 2\delta_{\alpha\delta} \delta_{\beta\gamma} - \frac{2}{N} \delta_{\alpha\beta} \delta_{\gamma\delta}, & \text{Tr}(\lambda^a \lambda^b \lambda^c) &= 2(d^{abc} + if^{abc}), \\ \text{Tr}(T_A^a T_A^b T_A^c) &= i \frac{N}{2} f^{abc}, & \sum_b d^{abb} &= 0, & d^{abc} d^{ebc} &= \left(N - \frac{4}{N}\right) \delta_{ae}, \\ f^{abe} f^{cde} + f^{ace} f^{dbe} + f^{ade} f^{bce} &= 0, & f^{abe} d^{cde} + f^{ace} d^{dbe} + f^{ade} d^{bce} &= 0. \end{aligned} \quad (\text{B.10})$$

Fig. C.1: Triangular quark loops generating the decay $\pi^0 \rightarrow \gamma\gamma$

C Anomalies

Our theoretical framework is based on the local gauge symmetry. However, so far we have discussed only the symmetries of the classical Lagrangian. It happens sometimes that a symmetry of \mathcal{L} gets broken by quantum effects, i.e., it is not a symmetry of the quantized theory; one says then that there is an ‘anomaly’. Anomalies appear in those symmetries involving both axial ($\bar{\psi}\gamma^\mu\gamma_5\psi$) and vector ($\bar{\psi}\gamma^\mu\psi$) currents, and reflect the impossibility of regularizing the quantum theory (the divergent loops) in a way which preserves the chiral (left/right) symmetries.

A priori there is nothing wrong with having an anomaly. In fact, sometimes they are even welcome. A good example is provided by the decay $\pi^0 \rightarrow \gamma\gamma$. There is a chiral symmetry of the QCD Lagrangian which forbids this transition; the π^0 should then be a stable particle, in contradiction with the experimental evidence. Fortunately, there is an anomaly generated by a triangular quark loop (Fig. C.1) which couples the axial current $A_\mu^3 \equiv (\bar{u}\gamma_\mu\gamma_5 u - \bar{d}\gamma_\mu\gamma_5 d)$ to two electromagnetic currents and breaks the conservation of the axial current at the quantum level:

$$\partial^\mu A_\mu^3 = \frac{\alpha}{4\pi} \epsilon^{\alpha\beta\sigma\rho} F_{\alpha\beta} F_{\sigma\rho} + \mathcal{O}(m_u + m_d). \quad (\text{C.1})$$

Since the π^0 couples to A_μ^3 , $\langle 0|A_\mu^3|\pi^0\rangle = 2i f_\pi p_\mu$, the $\pi^0 \rightarrow \gamma\gamma$ decay does finally occur, with a predicted rate

$$\Gamma(\pi^0 \rightarrow \gamma\gamma) = \left(\frac{N_C}{3}\right)^2 \frac{\alpha^2 m_\pi^3}{64\pi^3 f_\pi^2} = 7.73 \text{ eV}, \quad (\text{C.2})$$

where $N_C = 3$ denotes the number of quark colours and the so-called pion decay constant, $f_\pi = 92.4 \text{ MeV}$, is known from the $\pi^- \rightarrow \mu^- \bar{\nu}_\mu$ decay rate (assuming isospin symmetry). The agreement with the measured value, $\Gamma = 7.7 \pm 0.6 \text{ eV}$ [7], is excellent.

Anomalies are, however, very dangerous in the case of local gauge symmetries, because they destroy the renormalizability of the Quantum Field Theory. Since the $SU(2)_L \otimes U(1)_Y$ model is chiral (i.e., it distinguishes left from right), anomalies are clearly present. The gauge bosons couple to vector and axial-vector currents; we can then draw triangular diagrams with three arbitrary gauge bosons (W^\pm , Z , γ) in the external legs. Any such diagram involving one axial and two vector currents generates a breaking of the gauge symmetry. Thus, our nice model looks meaningless at the quantum level.

We have still one way out. What matters is not the value of a single Feynman diagram, but the sum of all possible contributions. The anomaly generated by the sum of all triangular diagrams connecting the three gauge bosons G_a , G_b and G_c is proportional to

$$\mathcal{A} = \text{Tr} \left(\{T^a, T^b\} T^c \right)_L - \text{Tr} \left(\{T^a, T^b\} T^c \right)_R, \quad (\text{C.3})$$

where the traces sum over all possible left- and right-handed fermions, respectively, running along the internal lines of the triangle. The matrices T^a are the generators associated with the corresponding gauge bosons; in our case, $T^a = \sigma_a/2$, Y .

In order to preserve the gauge symmetry, one needs a cancellation of all anomalous contributions, i.e., $\mathcal{A} = 0$. Since $\text{Tr}(\sigma_k) = 0$, we have an automatic cancellation in two combinations of generators: $\text{Tr}(\{\sigma_i, \sigma_j\} \sigma_k) = 2 \delta^{ij} \text{Tr}(\sigma_k) = 0$ and $\text{Tr}(\{Y, Y\} \sigma_k) \propto \text{Tr}(\sigma_k) = 0$. However, the other two

combinations $\text{Tr}(\{\sigma_i, \sigma_j\} Y)$ and $\text{Tr}(Y^3)$ turn out to be proportional to $\text{Tr}(Q)$, i.e., to the sum of fermion electric charges:

$$\sum_i Q_i = Q_e + Q_\nu + N_C (Q_u + Q_d) = -1 + \frac{1}{3} N_C = 0. \quad (\text{C.4})$$

Equation (C.4) conveys a very important message: the gauge symmetry of the $SU(2)_L \otimes U(1)_Y$ model does not have any quantum anomaly, provided that $N_C = 3$. Fortunately, this is precisely the right number of colours to understand strong interactions. Thus, at the quantum level, the electroweak model seems to know something about QCD. The complete SM gauge theory based on the group $SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$ is free of anomalies and, therefore, renormalizable. The anomaly cancellation involves one complete generation of leptons and quarks: ν , e , u , d . The SM would not make any sense with only leptons or quarks.
