## **Abstract**

T-cell intracellular antigen (TIA) proteins function as regulators of cell homeostasis by controlling global gene expression in response to dynamic regulatory changes and environmental stress. Here, we used two-dimensional differential in-gel electrophoresis (2D-DIGE) and mass spectrometry (MALDI-TOF/TOF) to identify protein changes associated with the down-regulated expression of TIA proteins. We detected 30 differentially expressed proteins (DEPs), 24 of which were identified, and some of these DEPs were validated by western blotting. *In silico* analysis showed that DEPs were associated with metabolic processes, detoxification and proteostasis. We mapped the DEPs to the available biological pathways and networks, which included the metabolism of small molecules such as sugars, lipids, amino acids, and nucleotides. Our findings support previous studies and suggest that low expression of TIA proteins might act as a potential adaptive switch to link gene expression reprogramming to a proliferative phenotype mediated by a hormesis phenomenon.

**Keywords:** TIA1, TIAR, proteome, adaptive metabolism, gene regulatory networks, TIA-hormesis.

## **Introduction**

T-cell intracellular antigen 1 (TIA1) and the closely related TIA1 related/like (TIAR/TIAL1) are multifunctional RNA-binding proteins involved in the fine-tuning of gene expression in the nucleus and cytoplasm through regulation of many aspects of RNA metabolism, including transcription, splicing/processing, subcellular localization, stability and translation [1-6]. Human TIA proteins bind to specific sequence motifs containing U-, CU-, and AU-rich RNA stretches on RNAs [1-4], and can regulate many properties of the human transcriptome [5,6].

While the roles of TIA-proteins in key cellular processes such as inflammatory and stress response are well recognized, less information is available for their involvement in proliferation/differentiation responses in pathophysiological conditions [1-6]. Nevertheless, it is known that knockdown of TIA1 and/or TIAR in various cell lines triggers proliferative phenotypes [5-11], suggesting that they may function as growth suppressors [5,6,9,12-18].

Two-dimensional polyacrylamide gel electrophoresis (2D-DIGE) is a core technology for protein separation and expression profiling [19,20,21], and is a useful tool for investigating the regulation of protein expression during pathophysiological situations [22]. Accordingly, proteome analysis coupled with systems biology approaches might predict new targets of TIA proteins and provide information on their role in different regulatory networks and homeostasis.

Herein, we used 2D-DIGE to investigate the consequences of reduced TIA expression in HeLa cells. We quantified differences and identified some of the proteins that were differentially expressed. The protein patterns found are consistent with adaptations of carbohydrate, amino acid, lipid, and nucleotide metabolism, free radical detoxification, and proteostasis.

## Material and Methods

### Sample preparation

HeLa cells were silenced for TIA1/TIAR (TIA) expression as described [9]. Four independent samples from control and TIA-knock down (kd) cells were prepared by differential centrifugation and stored at -80°C. Proteins were precipitated using the 2D Clean-up Kit (GE Healthcare) and resuspended in 30 mM Tris-HCl, 8 M urea, 2 M thiourea, 4% CHAPS (pH 8.5). Protein concentration was determined using the Bradford assay (Bio-Rad).

### Protein labeling

Four biological replicates were used from control and TIA-kd cells, generating eight individual samples. The 2D-DIGE was carried out at the Proteomics Facility, Universidad Complutense de Madrid-Parque Científico de Madrid. The samples were distributed across four DIGE gels, with the internal standard pooled sample also present, according to the experimental design shown in Figure 1. Proteins were fluorescently labeled following the protocol of the manufacturer (Sigma). Briefly, 400 pmol of Cy dye in 1 µl anhydrous *N,N*-dimethylformamide (Sigma) was used per 50 µg of protein. After 30 min of incubation on ice in the dark, the reaction was quenched with 1 µl of 10 mM lysine for 10 min.

### Electrophoresis and image acquisition

Labeled samples were combined according to the experimental design, processed and visualized with a Typhoon 9400 scanner (GE Healthcare) with CyDye filters as described previously [23,24]. For the Cy3, Cy5, and Cy2 image acquisition, 532/580, 633/670, and 488/520 nm excitation/emission wavelengths were used, respectively, and were acquired with a 100 µm pixel size.

### DIGE data analysis

Image analysis was carried out with DeCyder differential analysis software, version 6.5 (GE Healthcare) [23]. The differential in-gel analysis module was used to assign spot boundaries and to calculate parameters such as normalized spot volumes. The integral variability was corrected by normalization of the runs with the internal standard spot maps in the biological variation analysis module. The average ratio was calculated. The false discovery rate was applied to reduce the false positives in the *p*-value calculation [24]. Those protein spots with 1.5-fold as a threshold in the average ratio and with *P* values < 0.05 (Student's *t* test) were considered differentially expressed.

## **Protein identification by mass spectrometry**

The changes observed by 2D-DIGE analysis were aligned with Colloidal Coomassie Blue (CCB) profiling, and spots considered to be of interest were excised and in-gel digested [25]. After digestion, the supernatants were collected and 1 ml was spotted onto a matrix-assisted laser desorption ionization (MALDI) target plate and allowed to air-dry at room temperature. Then, 0.5  $\mu$ l of a 3 mg/ml  $\alpha$ -cyano-4-hydroxycinnamic acid matrix (Sigma) in 50% (vol/vol) acetonitrile and 0.1% trifluoroacetic acid was added to the dried peptide-digested spots and allowed to air dry.

Mass spectrometry (MS) analysis was performed in a MALDI-TOF/TOF spectrometer 4700 proteomics analyzer (PerSeptives Biosystems, Framingham, MA). The instrument was operated in reflector mode, with an accelerating voltage of 20,000 V. All mass spectra were internally calibrated using autodigested trypsin peptides. The mass fingerprint spectra with a signal-to-noise ratio greater than 20 were collated and represented as a list of monoisotopic molecular weights. Some proteins were subjected to MS/MS sequencing analysis to be more confident of the identification

For protein identification, the nonredundant NCBI database was searched using Mascot 2.1 ([www.matrixscience.com](http://www.matrixscience.com)) through the Global Protein Server, version 3.6 (Applied Biosystems). The Mascot search parameters were: (i) species: all; (ii) allowed number of missed cleavages: 1; (iii) carbamidomethyl cysteine as fixed modification; (iv) variable modification: methionine oxidation; (v) peptide tolerance:  $\pm$  50–80 ppm; (vi) MS/MS tolerance:  $\pm$  0.3 Da and (vii): peptide charge: +1. In all identified proteins, the probability score was greater than that fixed by Mascot as being significant ( $P < 0.05$ ). The parameters for the combined search (peptide mass fingerprint and MS/MS spectra) were the same as described above.

## **Western blotting**

Protein samples (10  $\mu$ g) were separated by 10% SDS-PAGE and transferred to a nylon membrane at 4°C and 50 V for 2 h. The membrane was then blocked with 5% powdered milk in phosphate-buffer saline solution (pH 7.5) containing 0.1% Tween-20 (Sigma) (PBS/T), then probed with specific antibodies against TAR DNA-binding protein 43 (TARDBP), aminoacylase-1 (ACY1), transkelotase (TKT), transaldolase (TALDO1), glyceraldehyde-3-P dehydrogenase (GAPDH), proliferating cell nuclear antigen (PCNA), beta subunit of actin (ACTB), citrate synthase (CS), T-cell intracellular antigen 1 (TIA1), TIA1 related/like protein (TIAR), and alpha subunit of tubulin (TUBA). Membranes were incubated with primary antibodies in PBS/T containing 3% BSA (Sigma) overnight at 4°C, washed, and then incubated with appropriate HRP-conjugated secondary antibodies at room temperature for 1 h. The ECL reagent (GE Healthcare) for HRP was used as a developer and band intensity was calculated by densitometry.

## **Bioinformatic analysis**

Ingenuity Pathway Analysis (IPA) (<http://apps.ingenuity.com>) was used to identify the pathways and networks of the identified proteins and to constitute molecular partners. Two master global networks of all differentially expressed proteins (DEPs) (input objects) were suggested according to published literature-based annotations, and further sub-networks were built from the master network to focus on activated targets and/or pathways. Biological functions, in terms of gene ontology (GO) and interaction networks, were also analyzed using IPA. Based on the local networks created by computational algorithms, identified proteins were connected with hub proteins,

forming a functional protein cluster. The heterogeneous set of DEPs was also analyzed using the Kyoto Encyclopedia of Genes and Genomes (KEGG) database. Analyses were performed using software programs provided by GenCodis3 (<http://genecodis.cnbc.csic.es>) [26,27], Bioprofiling (<http://bioprofilinig.de>) [28] and GeneAnalytics ([www.geneanalytics.com](http://www.geneanalytics.com)). Data from individual-nucleotide resolution UV crosslinking and immunoprecipitation (iCLIP) analysis of TIA1 and TIAR from HeLa cells were also used [4].

## Results and Discussion

### Identification of differentially expressed proteins in TIA-knockdown HeLa cells

To gain more insight into the role of TIA proteins in human cells, we compared the proteome of TIA-kd and control HeLa cells [9] using 2D-DIGE technology. The design involved mixing aliquots of every individual sample, which were included in equal amounts in the experiment. One-half of the samples of each condition were labeled with Cy3 dye, and the other one-half were labeled with Cy5 dye, to avoid any possible bias derived from the labeling efficiency. An internal standard sample was labeled with Cy2 dye and run on each gel. Thus, two samples from different replicates (Cy3 and Cy5) and an aliquot of the internal standard pool (Cy2) were separated by 2D electrophoresis in each one of the four gels. A scheme of the experimental design and the distribution of the samples is shown in Figure 1.

The four proteome samples were individually analyzed by 2D-DIGE, which resulted in the identification of ~1780 protein spots that tallied in the four gels. Among these were 30 protein spots that showed differential ratios with 1.5-fold change in abundance and consistent differences between the two backgrounds analyzed ( $P < 0.05$ ) (Figure S1). Twenty-one spots increased in intensity in TIA-kd cells, whereas nine decreased (Figure S1). Twenty-five of the 30 protein spots were excised and digested and the peptides were analyzed by MS. Two spots contained more than one protein; in these cases, the individual proteins were identified by MS/MS sequencing analysis (Figure S2). Table I summarizes the identified peptides including the average ratio and the statistical data from each comparison, as well as the data on Mascot identifications (Figure S2).

### Validation of predicted changes in proteomic analysis

We validated some of the 2D-DIGE data using western blotting to measure the expression of the following proteins linked to relevant biological processes or pathways: TARDBP, ACY1, TKT, TALDO1, GAPDH, PCNA, ACTB, CS, TIA1, TIAR, and TUBA. The results obtained were in part consistent with those of the proteomic analysis, suggesting that several changes observed in our proteomic analysis could represent putative novel targets of TIA proteins (Figure S3).

To gain a more complete view on the role of TIA proteins in gene expression control, the relative mRNA abundance of genes encoding for 23 of the proteins identified in the 2D-DIGE analysis were estimated from transcriptome profiles of control and TIA-kd cells using a previous genome-wide oligonucleotide-based DNA microarray analysis [29]. Six out of 23 DEPs (TKT, G6PD, IDH1, AKR1C2, AKR1C3 and CS) corresponded to genes that were differentially decreased in the transcriptomic assay [29], suggesting that their regulation was exerted *via* controlling their rates of transcription, alternative pre-mRNA splicing, and/or mRNA stability/turnover. The remainder of the genes showed unaltered mRNA levels, suggesting that their differential expression could reflect a post-transcriptional control *via* modulating the rates of mRNA translation and/or protein stability.

In the light of the above data, a question emerges as to how the under-expression of TIA proteins in HeLa cells can regulate the expression of so many functionally related genes. One possibility is that these mRNAs or their precursors (pre-mRNAs) could be targeted by TIA proteins at different levels to control their gene expression. In this regard, the experimental profiles of TIA1 and TIAR proteins (Figure 2 and S4) were examined using the iCLIP database of TIA proteins, kindly provided by the Ule lab [4]. The results showed that many of the gene targets identified contain multiple TIA-binding sites located across the full-length pre-mRNAs, both exons and introns, with a high frequency in the last exons and particularly at the 3'-untranslated regions of the mature mRNAs. Therefore, many of these mRNAs might be TIA-target genes that are subject to post-transcriptional and/or translational regulation. Pre-mRNAs and/or mRNAs are tethered to regulatory factors, and the combinatorial binding of these RNA-binding proteins and/or microRNAs to mRNA targets coordinates different steps of RNA metabolism [6]. It will be important to determine whether ectopic and/or endogenous TIA protein expression, as well as potential post-translational modifications of these factors, can also regulate the gene expression patterns of these target mRNAs at transcriptional and/or post-transcriptional levels. Our observations suggest a direct interaction between some mRNAs and TIA proteins, which could contribute to the post-transcriptional regulation of these targets, indicating that these multifunctional regulators are able to function as global and/or specific translational repressors, possibly by temporarily contributing to plasticity in growth and metabolism that enables cells/tissues to adapt/survive in a dynamic environment.

### Classification of differentially expressed genes

Proteins were classified according to biological processes as described in the protein knowledge base (UniProtKB) ([www.uniprot.org](http://www.uniprot.org)) (Table I). We used IPA to map the biological functions, pathways and networks for the 30 DEPs. The analysis highlighted several metabolic pathways including pentose phosphate pathway (non-oxidative and oxidative branch), TCA cycle, amino acid turnover and/or biosynthesis, and NADH repair (Figure 3A). Canonical pathways identified at statistically significant levels ( $P < 0.05$ ) are shown in Figure 3A. The scores (-log [p values]) reflect the probabilities of such associations occurring by chance, with the threshold value for significance set at 1.25. Cellular compartments as designated by IPA (GO-based) indicated that the majority of identified proteins were cytoplasmic and mitochondrial in origin (data not shown).

GO analysis identified the main categories of biological processes and molecular functions of DEPs controlled by TIA proteins (Figures S5 and S6). GO categories related to small molecule and carbohydrate metabolic processes, citric acid cycle (TCA cycle) and pentose-phosphate, among others, were especially prevalent among the enriched categories of "Biological Process and Molecular Function" (Figures S5 and S6). KEGG/pathways database analysis was used to identify the enrichment of specific pathways in functionally regulated gene groups. Several KEGG pathways were significantly enriched in regulated/modulated proteins, including those involved in carbon, glucose and energy metabolism, pentose-phosphate pathway, MPS VI-Maroteaux-Lamy syndrome, (TCA cycle) and glyoxylate and dicarboxylate metabolism. In addition, several human diseases clustered as global and anatomical categories were related with the differentially expressed proteins: global categories were associated with rare, genetic, infectious, cancer and fetal diseases; and anatomical categories were

linked to neuronal, bone, blood, skin, eye, nephrological, liver, mental, muscle, reproductive, respiratory, ear, gastrointestinal, endocrine, cardiovascular and immune diseases. Furthermore, several pathophysiological aspects were also associated with the genes identified, such as liver disease, asthma, allergy, arthritis, congenital dyserythropoietic anemia, distant metastasis, carcinoma (breast, renal and colon), leukemia, coronary heart disease, insulin resistance (diabetes) and obesity (data not shown). Bioprofiling tool analysis showed that most of DEPs are implicated in carbohydrate and small molecule metabolic processes in cytoplasm related to the metabolism of amino acids, sugars and nucleotides. Taken together, these observations suggest that most of the genes are implicated in the metabolism of sugars, nucleotides, and amino acids as well as in metabolism-associated diseases. These *in silico* analysis were completed with integration analysis using IPA to build gene networks. The results obtained showed a top-scoring network connecting 18 DEPs (11 up- and 7-down-regulated genes) strongly linked to metabolic and proteostasis features (Figure 3B). A secondary subnetwork involving only 7 up-regulated DEPs was associated with detoxification and metabolism (Figure S7). Thus, metabolism, proteostasis, and detoxification dynamics appear as hallmarks in all the analyses performed (Figure 3 and S5-S7).

Cellular metabolism is generally a primary target to favor the development and establishment of new cellular phenotypes. For example, cells with higher proliferative capacity reprogram basal metabolism to adapt to the new requirements associated with phenotypic evolution. Against this background, at least two metabolic aspects are fundamental: how cellular energy is derived and what are the sources. Thus, depending on whether oxygen availability is sufficient, glycolysis provides energy in the form of ATP, precursors for the synthesis of amino acids (for protein biosynthesis), nucleotides (for the processes of synthesis and replication of cellular DNA and DNA-dependent transcription), lipids (for the synthesis of biological membranes), and reducing power (to achieve the synthesis of the above precursors) [30]. Furthermore, mitochondria also play an essential role in metabolic renewal and the processes associated with this organelle are readapted, favoring the production of anabolic precursors to the detriment of the production of energy [31]. Mitochondria also contribute to intracellular signaling, retrograde communication and detoxification at this regulatory crossroads, to make possible the acquisition of a stronger proliferative phenotype [30,31].

Mice lacking both TIA1 and TIAR are nonviable and die before embryonic day 7, implying that at least one of these proteins is necessary for normal embryonic development [32,33]. HEK293 cells with CRISPR-mediated deletion of TIA1 present a chronic stress response mediated by the EIF2AK2 kinase, triggering cell-cycle arrest at G2/M phase, and a progressive DNA damage response that enhances cell death after 7 days [34]. By contrast, several cell models with reduced expression of TIA1 and/or TIAR by RNA interference mainly show an adaptive response accompanied by a proliferative phenotype [5-13]. This is reminiscent of that observed when a low dose of a stressful stimulus activates an adaptive response that increases the resistance of the cell or organism to higher stress levels [35]. Therefore, we propose that in cases of low TIA expression, there is an adaptive response known as hormesis. Accordingly, TIA-associated hormetic response involves the expression of genes that encode cytoprotective proteins such as metabolic and antioxidant enzymes, chaperones, and survival factors.

Crosstalk of gene expression regulation associated with TIA proteins may involve complex autoregulatory loops with key factors such as other RNA-binding proteins [36]. For example, TIA proteins are recognized transcriptional and post-transcriptional regulators [6], yet, both their overexpression and knockdown increase stress granule formation [37,38]. Such positive and negative assembly roles for TIA proteins could be determined by cellular conditions, by their overall concentration, or be a consequence of altered regulation of other stress granule assembly factors, such as TIA1, whose translation and alternative splicing is regulated by TIAR [39,40]. By contrast, the RNA binding protein HuR, which is operatively close to TIA proteins, enhances TIA1 expression [39]. Given these types of regulatory hubs, care must be exercised in interpreting loss- and gain-of-function phenotypes without a clear understanding of the underlying mechanism [36]. In addition, distinct size changes to 3'-untranslated regions (UTR) have been recently described under stress conditions in proliferating and differentiated cells, correlating with stress granule association and mRNA decay of long 3'-UTR isoforms in a TIA1-dependent manner. This observation underlies a context-specific impact on the 3'UTR landscape associated with TIA1 expression [41].

The bar graphs show the number of cDNAs that identified each

crosslinking site. The localization of target genes on human chromosomes and the exon and intron positions of the human pre-mRNAs are shown. The following gene names are used: LMNB1, lamin-B1; TARDBP, TAR DNA-binding protein 43; EIF2B2, eIF-2B subunit beta; PSMB8, proteasome subunit  $\beta$  type-8; SELENBP1, selenium-binding protein 1; PRDX2, peroxiredoxin-2; TKT, transkelotase; G6PD, glucose-6-phosphate 1-dehydrogenase; TALDO1, transaldolase; GAPDH, glyceraldehyde-3-P; CS, citrate synthase; GOT1, aspartate aminotransferase.

**Figure 3. The top-scoring regulatory networks identified by Ingenuity Pathway Analysis.** (A) IPA of biological processes associated with differentially expressed proteins (DEPs) in TIA-kd HeLa cells. The classical IPA bar chart displays biological functions along the x-axis. The y-axis displays the - (log) significance ( $-\log P$  values) calculated by Fisher's exact test ( $P < 0.05$ ). Functions are listed from most (higher bars) to least (lower bars) significant and the orange horizontal line denotes the threshold for significance ( $P = 0.05$ ). (B) DEPs that are upregulated and downregulated in TIA-kd HeLa cells are displayed within red and green nodes, respectively. The intensity of the shading shows to what degree each gene was up or downregulated. Solid and dashed lines between genes represent known direct and indirect gene interactions, respectively. The shapes of the nodes reflect the functional class of each gene product: transcriptional regulator (horizontal ellipse), transmembrane receptor (vertical ellipse), enzyme (vertical rhombus), cytokine/growth factor (square), kinase (inverted triangle) and complex/group/other (circle). The following colored gene names are shown: AKR1C1, aldo-keto reductase 1 C1; AKR1C2, aldo-keto reductase 1 C2; AKR1C3, aldo-keto reductase 1 C3; CAT, catalase; CS, citrate synthase; CRKL, Crk-like protein; EIF2B2, eIF-2B subunit beta; G6PD, glucose-6-phosphate 1-dehydrogenase; GAPDH, glyceraldehyde-3-P dehydrogenase; GOT1, aspartate aminotransferase; HSPA8, heat shock cognate 71 kDa; IDH1, isocitrate DH [NADP], IDH3A, isocitrate DH [NAD] alpha; PRDX2, peroxiredoxin-2; PSMB8, proteasome subunit  $\beta$  type-8; TALDO1, transaldolase; TARDBP, TAR DNA-binding protein 43; BLVRA, biliverdin reductase A; MDH1, malate dehydrogenase.

**Table I. Summary of the identified proteins classified according to biological function, with the average ratio, statistical data from the comparison and the data from Mascot identifications.** <sup>(a)</sup>Average volume ratio TIA1 + TIAR/control and t test P value, quantified by DeCyder BVA module. <sup>(b)</sup>Score: Mascot MS protein score or MS/MS, obtained from MALDI-TOF/TOF spectra. In all of the cases, a probability score of  $< 0.05$  was obtained. <sup>(c)</sup>Number of peptide mass value searched/mapped. <sup>(d)</sup>Amino acid sequence coverage for the identified proteins or sequence identified by MS/MS.

GN=TKT PE=1 SV=3

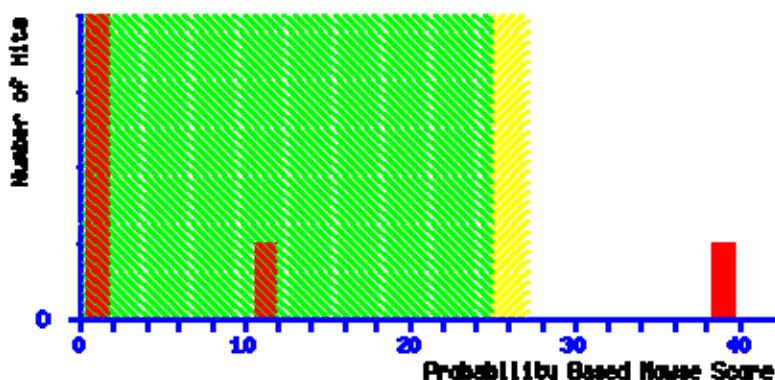

## Probability Based Mowse Score

Ions score is  $-10 \cdot \log(P)$ , where P is the probability that the observed match is a random event.

Individual ions scores > 25 indicate peptides with significant homology.

Individual ions scores > 27 indicate identity or extensive homology ( $p < 0.05$ ).

Protein scores are derived from ions scores as a non-probabilistic basis for ranking protein hits.
