#### Abstract

The vibrational and structural behaviors of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ orthovanadates have been studied up to around 20 GPa by means of X-ray diffraction, Raman spectra, and theoretical simulations. Both materials crystallize in an orthorhombic Kagomé staircase structure (space group: Cmca) at ambient conditions, and no phase transition was found in the whole pressure range. In order to identify the symmetry of the detected Raman-active modes under high pressure, single crystal samples of those materials were used in a polarized Raman and infrared setup. Moreover, high-pressure powder X-ray diffraction measurements were performed for $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, and the results confirmed the structure stability also obtained by other diagnostic techniques. From this XRD analysis, the anisotropic compressibilities of all axes were calculated and the unit-cell volume vs pressure was fitted by a Birch-Murnaghan equation of state, obtaining a bulk modulus of 122 GPa .

## 1. INTRODUCTION

Metal orthovanadates following the formula $\mathrm{M}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}(\mathrm{M}=\mathrm{Ni}$, $\mathrm{Co}, \mathrm{Zn}, \mathrm{Mn}$, and Mg ) have attracted considerable fundamental research attention for decades, ${ }^{1-3}$ due to their rich polymorphism ${ }^{4-7}$ and multiferroic properties. ${ }^{8-10}$ These qualities make them desirable materials for industrial applications. Regarding the samples studied in this work, Ni and Co orthovanadates are mainly used in nanostructured systems. Both have been investigated as catalysts in the water splitting process, ${ }^{11,12}$ as electrodes in portable power sources, ${ }^{13,14}$ in the potential improvement of electrochemical energy storage, ${ }^{15,16}$ in nitrogen fixation, ${ }^{17}$ and even in glucose detection. ${ }^{18}$
The so-called Kagomé-staircase orthorhombic structure of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ (space group: Cmca, No. 64) is formed by corrugated layers in the [010] direction of edge-sharing $\mathrm{MO}_{6}$ octahedra interconnected with $\mathrm{VO}_{4}$ tetrahedra (see Figure 1). Both compounds have four formulas per unit cell ( $Z$ = 4). The lattice parameters for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ are $a=5.936(4) \AA, b$ $=11.420(6) \AA$, and $c=8.240(5) \AA$ and for $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ are $a=$ 6.030(4) $\AA, b=11.486(2) \AA$, and $c=8.312(5) \AA .{ }^{1}$ It is worth mentioning that a similar polyhedral coordination is also found in metavanadates $\left(\mathrm{MV}_{2} \mathrm{O}_{6}\right)^{19}$ and pyrovanadates $\left.\left(\mathrm{M}_{2} \mathrm{~V}_{2} \mathrm{O}_{7}\right)\right)^{20}$
In recent years, the high pressure ( HP ) community has also put the focus on this family of compounds, which have demonstrated a variety of remarkable physical behaviors under pressure. X-ray diffraction (XRD) and Raman methods were used to study $\mathrm{Mn}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ in its orthorhombic low-temperature

Figure 1. Crystal structure of the $\mathrm{M}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ orthovanadate Kagoméstaircase family. Atoms and unit-cell axis are labeled on the left. $\mathrm{MO}_{6}$ octahedra are shown in blue, and $\mathrm{VO}_{4}$ tetrahedra are shown in green.

[^0]
structure; an irreversible phase transition at 10 GPa was discovered, but the new phase has not been identified yet. ${ }^{21}$ In contrast, it has been demonstrated that $\mathrm{Zn}, \mathrm{Ni}$, and Mg orthovanadates are stable up to $15,{ }^{22} 23,{ }^{23}$ and 25.7 GPa , ${ }^{24}$ respectively. With different structures but the same stoichiometry, Ca and Sr orthovanadates were found to undergo different phase transitions at $9.7(1) \mathrm{GPa}^{25}$ and $13.8 \mathrm{GPa}{ }^{26}$ respectively. Alternatively, it was reported that triclinic $\mathrm{Cu}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ decomposes into CuO and $\mathrm{V}_{2} \mathrm{O}_{5}$ at $1.35 \mathrm{GPa} .{ }^{27}$ Note that the structural properties of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ were recently investigated by HP powder XRD by some of the authors of the present study. ${ }^{24}$ To compare with $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, the data from that work are included in the current investigation.
We continue the research in orthovanadates within this paper by reporting for the first time the changes in the vibrational modes of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ under HP from both experiments and density functional theory (DFT) calculations. As a previous step, polarized Raman and infrared (IR) measurements are used to properly identify the symmetry of the active modes and match them with the simulation results under ambient conditions. We also present the first HP XRD analyses of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. As it is situated in the periodic table between Mn (which undergoes a phase transition at $10 \mathrm{GPa}^{21}$ ) and Ni (which remains stable up to $23 \mathrm{GPa}^{23}$ ), it is of great interest to find out what structural changes occur under pressure. The experimental data are also supported by the corresponding DFT calculations. We determined the bulk modulus and anisotropic compressibility of this compound from the structural information we have collected. Finally, we make use of all the results obtained to compare the pressure behavior of both orthovanadates.

## 2. METHODS

2.1. Sample Synthesis. Powder samples of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8} /$ $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ were synthesized by means of a solid-state reaction starting with $\mathrm{NiO} / \mathrm{CoO}$ ( $99.995 \%$ purity) and $\mathrm{V}_{2} \mathrm{O}_{5}$ ( $99.9 \%$ purity). The precursors were obtained from Alfa Aesar. An $\mathrm{Al}_{2} \mathrm{O}_{3}$ crucible was used to heat the mixed reagents in air at $800^{\circ} \mathrm{C}$ for 16 h . The product was then ground and pressed into a pellet, which was sintered at $900^{\circ} \mathrm{C}$ for an additional 16 h.

For the single crystal preparation, $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8} / \mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ powders were prepared at $900{ }^{\circ} \mathrm{C}$ for 40 h by a standard/ high-temperature solid-state reaction method using $\mathrm{NiC}_{2} \mathrm{O}_{4}$. $2 \mathrm{H}_{2} \mathrm{O} / \mathrm{CoC}_{2} \mathrm{O}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{V}_{2} \mathrm{O}_{5}$ as the reagents with a molar ratio of $3: 1$. The crystal growth was performed in an electric furnace, where $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8} / \mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ powder samples and flux $\mathrm{V}_{2} \mathrm{O}_{5}$ and $\mathrm{SrCO}_{3}$ (also $\mathrm{BaCO}_{3}$ for $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ ) were melted homogeneously in an alumina crucible at $1000^{\circ} \mathrm{C}$ and kept at $1000{ }^{\circ} \mathrm{C}$ for 10 h , cooled slowly to $800^{\circ} \mathrm{C} / 700^{\circ} \mathrm{C}$ at a rate of $0.5^{\circ} \mathrm{C} / \mathrm{h}$ (making constant temperature stops several times in between), and finally cooled to room temperature at a rate of approximately $100^{\circ} \mathrm{C} / \mathrm{h}$. The final Ni yellow crystals $(\sim 3 \times 3$ $\left.\times 0.5 \mathrm{~mm}^{3}\right) /$ Co dark blue crystals $\left(\sim 4 \times 4 \times 1 \mathrm{~mm}^{3}\right)$ were obtained by mechanical separation from the crucible. A detailed growth procedure is described in ref 28 for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and in ref 29 for $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$.
2.2. Experimental Details. The orientation of the single crystals was carried out by using a Bruker D8 Venture diffractometer. IR spectra at ambient conditions were collected with an FTIR Bruker IFS125 HR spectrometer using a Globar light source, KBr beam splitter, and MCT detector (cut at 600 $\mathrm{cm}^{-1}$ ). Raman spectra were acquired in the backscattering
geometry using a $632.8 \mathrm{~nm} \mathrm{He}-\mathrm{Ne}$ laser, a Jobin Yvon spectrometer combined with a thermoelectric-cooled multichannel charge-coupled device (CCD) detector with a spectral resolution of $2 \mathrm{~cm}^{-1}$, and a Semrock low-pass RazorEdge filter. A low laser power of approximately 2 mW before the diamond anvil cell (DAC) was necessary to avoid overheating the sample and wavenumber shifting. Polarizer filters were added to the Raman setup for the single crystal measurements. HP Raman measurements were performed using a DAC and a 16:3:1 methanol-ethanol-water mixture as the pressuretransmitting medium (PTM). ${ }^{30}$ The peak profile fit was achieved using a Pseudo-Voight peak profile in MATLAB software. ${ }^{31}$ The pressure gauge was determined using ruby luminescence. ${ }^{32}$

HP powder XRD measurements on $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ were performed at the MSPD beamline of the ALBA synchrotron ${ }^{33}$ using a monochromatic beam with a wavelength of 0.4246 Å. The beam was focused down to a spot with a full width at halfmaximum (fwhm) of $20 \mu \mathrm{~m} \times 20 \mu \mathrm{~m}$. A Rayonix CCD detector was used to collect XRD patterns with a sample-todetector distance of 340 mm . This sample-detector distance was required to achieve a correct angular resolution, which limited our $2 \theta$ range to around $13^{\circ}$. The pressure was determined using the XRD reflections and the equation of state (EOS) of $\mathrm{Cu}^{34}$ with a precision of $\pm 0.1 \mathrm{GPa}$. The PTM used for these experiments was a $4: 1$ methanol-ethanol (ME) mixture. The measurements thus obtained were transformed into one-dimensional patterns using the DIOPTAS suite, ${ }^{35}$ and Le Bail fittings were achieved with PowderCell. ${ }^{36}$
2.3. Ab Initio Density-Functional Theory Calculations. Ab initio calculations were performed within the framework of density functional theory (DFT) ${ }^{37}$ with the Vienna ab initio Simulation Package (VASP). ${ }^{38,39}$ The projector augmentedwave (PAW) method ${ }^{40,41}$ was employed. To ensure accurate converged results, the plane-wave kinetic cutoff was extended up to 650 and 540 eV for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, respectively. The integrations over the Brillouin zone ( $\mathrm{BZ} \mathrm{)} \mathrm{were} \mathrm{carried} \mathrm{out}$ with a k-special point sampling grid of $6 \times 6 \times 4$. After testing different functionals to decide which was the most accurate for each compound, the exchange-correlation energy was described by means of the generalized gradient approximation (GGA) with the Armiento and Mattsson (AM05) prescription ${ }^{42,43}$ for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and, in the case of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, the Perdew-Burke-Ernzerhof (PBE) functional for solids. ${ }^{44,45}$ To properly treat the strongly correlated states, the DFT +U method of Duradev et al. ${ }^{46}$ was employed. This method utilizes a single parameter, $U_{\text {eff }}=U-J$, where $U$ and $J$ are the effective on-site Coulomb and exchange parameters, respectively. The values used for $U_{\text {eff }}{ }^{47}$ were 6.2 eV for $\mathrm{Ni}, 3.25 \mathrm{eV}$ for V , and 3.32 eV for Co. In both compounds, the ferromagnetic configuration was found to be lower in energy.

The unit cell parameters and atomic positions were fully optimized to obtain, at selected volumes, the relaxed structure. For the optimization, the criteria used were as follows: the forces on the atoms were less than $3 \mathrm{meV} / \AA$, and the deviations of the stress tensors from a diagonal hydrostatic form were lower than 0.1 GPa . Our ab initio calculations provide a data set of volumes, energies, and pressures (from the stress tensor) that are fitted with a Birch-Murnaghan equation of state ${ }^{48}$ to obtain the theoretical equilibrium volume, the bulk modulus, and the pressure derivatives.

Lattice-dynamic calculations of the phonon modes were carried out at the zone center ( $\Gamma$ point) of the BZ with the
direct force-constant approach provided by Phonopy. ${ }^{49}$ These calculations provide the frequency of the normal modes, their symmetry, and their polarization vectors. This allows the identification of the irreducible representations and character of the phonon modes at the $\Gamma$-point. To include the polarization induced by atomic displacements and the generated macroscopic electric field producing the $\mathrm{LO} / \mathrm{TO}$ splitting, the nonanalytical term corrections were added using a $2 \times 2 \times 2$ supercell, with the Born effective charges and the dielectric tensor as described in the Phonopy package. ${ }^{49}$

## 3. RESULTS AND DISCUSSION

3.1. Vibrational Properties of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. Both Ni and Co orthovanadates present the same crystalline

${ }^{a} \gamma_{0}$ is the damping factor of the fitting in $\mathrm{cm}^{-1}$, and $\omega_{0}$ is expressed in $\mathrm{cm}^{-1}$. The DFT-calculated $\omega_{0}$ has a related uncertainty of $\pm 5 \%$.

Figure 4. Symmetry assignment of the Raman modes of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ at ambient conditions. The vertical ticks represent the DFT calculation results, matching in color with the corresponding symmetry. The incidence direction $\xi$ of the tilted sample is sketched. If any magnification or reduction factor is applied to the data region, it is labeled next to it.

The modes with the largest wavenumbers are related to the internal modes of the $\mathrm{VO}_{4}$ tetrahedra. Taking a closer look into some of the representative modes (referring to the wavenumbers of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ ), it can be seen that $\mathrm{A}_{\mathrm{g}}^{9}$ (Figure 2) and $\mathrm{B}_{1 \mathrm{u}}^{12}$ are $\mathrm{V}-\mathrm{O}$ bond stretching modes. Both have very similar calculated frequencies ( 789 and $770 \mathrm{~cm}^{-1}$, respectively), because their vibration pattern is very similar, but the inversion center makes the equivalent V and O movement through this point in phase or in phase opposition. Other examples of phonons related to the internal movement of the tetrahedra are the $B_{3 g}^{9}$, Figure 2, and $B_{2 u}^{10}$ modes ( 670 and $642 \mathrm{~cm}^{-1}$, respectively). Their vibration pattern includes bending of $\mathrm{V}-\mathrm{O}$ bonds. From 640 to $440 \mathrm{~cm}^{-1}$, there is a frequency gap that divides internal from external modes. The more energetic mode with a relevant Co amplitude is the $A_{u}^{7}$ mode at 460 $\mathrm{cm}^{-1}$. The amplitude is, however, not large enough to be appreciated in Table S3. It is remarkable that internal modes have similar frequencies in Co and Ni compounds (a difference of less than $4 \%$ ). In external modes where the $M$ amplitude is
relevant, the wavenumber differences are more pronounced. The mode with the largest Co amplitude is the $\mathrm{B}_{1 \mathrm{u}}^{2}$ mode. The wavenumbers in Co and Ni compounds differ by 16\% (124 and $144 \mathrm{~cm}^{-1}$, respectively). The mode $\mathrm{B}_{3 \mathrm{u}}^{2}\left(144 \mathrm{~cm}^{-1}\right.$ in the Co compound) constitutes an example of rotation of the $\mathrm{VO}_{4}$ tetrahedron, in this case having a $\mathrm{V}-\mathrm{O}$ bond as an axis, Figure 2. The mode also involves a significant shift of the Co atoms. Finally, the low wavenumber mode $A_{\mathrm{g}}^{1}\left(111 \mathrm{~cm}^{-1}\right.$, Figure 2) represents a mode where atoms in a plane roughly defined by $z$ $\cong 0.25$ vibrate in phase opposition respect to atoms in a $z \cong$ 0.75 plane, while atoms near $z=0$ and 0.5 remain static. The large mass involved implies low frequency mode. Other similar modes are $B_{1 \mathrm{u}}^{2}\left(124 \mathrm{~cm}^{-1}\right)$ and $\mathrm{B}_{1 \mathrm{~g}}^{1}\left(121 \mathrm{~cm}^{-1}\right)$.

### 3.2. Ambient Conditions for Infrared Spectroscopy

 $\left(\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}\right.$ and $\left.\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}\right)$. IR modes were identified using polarization and considering that $\mathrm{B}_{1 \mathrm{w}}, \mathrm{B}_{2 \mathrm{w}}$ and $\mathrm{B}_{3 \mathrm{u}}$ modes transform as $z, y$, and $x$, respectively. The ab initio calculated IR active modes, including the transversal optic (TO) and longitudinal optic (LO) splittings and the corresponding pressure coefficients, are reported in Table 1. Furthermore, in Table 2, using the theoretical IR phonon wavenumbers and the simulated static dielectric constants $\left(\varepsilon_{0}\right)$, the infinite dielectric constants ( $\varepsilon_{\infty}$ ) were calculated using the Lyddane-Sachs Teller relation. ${ }^{51}$The growth conditions of the samples favored the formation of single crystals with the largest surface perpendicular to the $y$ axis. The measurements were taken on the [010] surface. The spectral region for the present IR measurements covered from 600 to $4500 \mathrm{~cm}^{-1}$. Therefore, only the three highest frequency $B_{1 u}$ modes and the last $B_{3 u}$ for both $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ single crystals were accessible. These modes were selected using polarizers, as represented in Figure 3. The dielectric constant was modeled using the following relation:

$$
\begin{equation*}
\varepsilon=\varepsilon_{\infty} \prod_{\mathrm{j}} \frac{\omega_{\mathrm{LO}, \mathrm{j}}{ }^{2}-\omega^{2}+i \gamma_{\mathrm{LO}, j} \omega}{\omega_{\mathrm{TO}, \mathrm{j}}{ }^{2}-\omega^{2}+i \gamma_{\mathrm{TO}, j} \omega} \tag{1}
\end{equation*}
$$

where $\omega_{\mathrm{TO}}, \omega_{\mathrm{LO}}, \gamma_{\mathrm{TO}}$, and $\gamma_{\mathrm{LO}}$ are the frequencies and damping factors of the transverse and longitudinal optic modes, respectively. ${ }^{52}$ Using eq 1 , the reflectivity of the material, $R=|(\sqrt{\varepsilon}-1) /(\sqrt{\varepsilon}+1)|^{2}$, can be obtained, and then, the total reflectance of the sample can be calculated, considering that the body with parallel surfaces undergoes consecutive internal reflections, as follows:

$$
\begin{equation*}
\frac{I_{\mathrm{R}}}{I_{0}}=R+\frac{(1-R)^{2} R e^{-\alpha d}}{1-R^{2} e^{-2 \alpha d}} \tag{2}
\end{equation*}
$$

where $\alpha$ is the absorption coefficient. Equation 2 was used to fit the experimental data in Figure 3. In the spectral region where the sample is transparent, this expression simplifies to

$$
\begin{equation*}
\frac{I_{\mathrm{R}}}{I_{0}}=\frac{2 R}{1+R} \tag{3}
\end{equation*}
$$

The criteria chosen for data normalization are based on the reflectance (3) at $4500 \mathrm{~cm}^{-1}$, where the sample is transparent and the reflectance is estimated using the calculated static dielectric constant from Table 2.

The experimentally determined IR modes are gathered along with the calculated modes in Table 3. It is noticeable that both experimental and theoretical values are in good agreement, including the TO-LO splitting values.

Table 4. Raman Modes, Wavenumbers, and Pressure Coefficients Corresponding to the Zone-Center Active Raman Modes under Ambient Conditions for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}{ }^{a}$

${ }^{a} \omega_{0}$ is expressed in $\mathrm{cm}^{-1}$, and $P$, in GPa. The DFT-calculated $\omega_{0}$ has a related uncertainty of $\pm 5 \%$. Discrepancies in symmetry assignation with Kesari et al. ${ }^{53}$ are included in its column.

### 3.3. Ambient Conditions for Polarized Raman

 $\left(\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}\right.$ and $\left.\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}\right)$. First, the Raman tensors of the allowed modes are ${ }^{50}$$$
\begin{aligned}
& A_{g}=\left(\begin{array}{lll}
a & 0 & 0 \\
0 & b & 0 \\
0 & 0 & c
\end{array}\right), B_{1 g}=\left(\begin{array}{lll}
0 & d & 0 \\
d & 0 & 0 \\
0 & 0 & 0
\end{array}\right), B_{2 g}=\left(\begin{array}{lll}
0 & 0 & e \\
0 & 0 & 0 \\
\mathrm{e} & 0 & 0
\end{array}\right) \\
& \text { and } B_{3 g}=\left(\begin{array}{lll}
0 & 0 & 0 \\
0 & 0 & f \\
0 & f & 0
\end{array}\right)
\end{aligned}
$$

The resulting selection rules provide the advantage of being able to measure the modes separately, always in the backscattering configuration, employing the previously oriented single crystals. Additionally, it must be noted that $\mathrm{A}_{\mathrm{g}}$ and $\mathrm{B}_{1 \mathrm{~g}} / \mathrm{B}_{2 \mathrm{~g}} / \mathrm{B}_{3 \mathrm{~g}}$ modes are allowed when the backscattered signal from the single crystal sample is polarized parallel or
perpendicular to the polarization of the incident laser, respectively. On the other hand, $\mathrm{B}_{1 g} / \mathrm{B}_{2 \mathrm{~g}} / \mathrm{B}_{3 \mathrm{~g}}$ modes can only be measured if the surface of incidence is oriented in the crystallographic $c / b / a$-axis (hereon referred to as $z / y / x$ ). Depending on the specimen, other smaller surfaces different from [010] were also available. In the case of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, a single crystal with a small [001] face was measured. In addition, a third perpendicular surface could be measured, starting from the [010] plane and tilting the DAC $53^{\circ}$ with respect to the $z$ axis (from now on called the $\xi$ orientation; see Figure 4), which yielded a spectrum containing $B_{1 g}$ and $B_{3 g}$ modes. In the case of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, only the [010] and [001] surfaces were available. The Raman characterization of both compounds at room temperature was completed with a powder spectrum.

The complete symmetry phonon assignment for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ is shown in Figure 4. All $10 \mathrm{~A}_{\mathrm{g}}$ modes were found using coincident polarization in all 3 orientations of the crystal (except for $\mathrm{A}_{\mathrm{g}}^{2}$, which was found only in the $\xi$ orientation).

Figure 5. Symmetry assignment of the Raman modes of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ at ambient conditions. The vertical ticks represent the DFT calculation results, matching in color with the corresponding symmetry. The magnification of the low wavenumber region is $20 \times$.

Figure 6. Raman spectra corresponding to $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ at selected pressures. The symmetry modes are assigned colors in the first pattern. Numbers next to the spectra indicate pressure in GPa. Downstroke data are marked with a " d ". Magnification of the first region is shown in the top left corner.

Using crossed polarization, the $B_{1 g}$ modes were identified when inciding along the $z$-axis ( 6 out of 8 ), $\mathrm{B}_{2 \mathrm{~g}}$ modes, with $y$ incidence ( 6 out of 7 ), and a mixture of $B_{1 g}$ and $B_{3 g}$, in the $\xi$ axis ( 7 out of the 11 total $B_{3 g}$ ). There was no polarization leakage in any of the spectra, except for the most intense mode, $\mathrm{A}_{\mathrm{g}}^{10}$, which was also measured in crossed polarization at orientations $z$ and $\xi$. Thus, a total of 29 modes of the 36

Figure 7. Raman spectra corresponding to $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ at selected pressures. The symmetry modes are assigned colors in the first pattern. Numbers next to the spectra indicate pressure in GPa. Downstroke data are marked with a " d ". Magnification of the first region is shown in the top left corner.

Raman-active modes are reported. Kesari et al. found 30 modes experimentally and performed DFT calculations. ${ }^{53}$ Overall, this work is in good agreement with this study, except that the symmetry of some nearby modes are not assigned in the same way (see $B_{1 g}^{3}-B_{2 g}^{2}-B_{3 g}^{1}, A_{g}^{4}-B_{1 g}^{4}-B_{2 g}^{3}, A_{g}^{5}-B_{1 g}^{5}, B_{1 g}^{6}-B_{3 g}^{6}, A_{g}^{7}-B_{3 g}^{8}, A_{g}^{9}-B_{g}^{6}$, and $\mathrm{A}_{\mathrm{g}}^{10}-\mathrm{B}_{3 \mathrm{~g}}^{11}$ in Table 4), and not all the modes detected are the same. Combining both works, there are only 3 modes not detected experimentally. The analogue study for $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ can be seen in Figure 5, which was less successful in comparison with the Ni compound due to its higher absorption of the excitation laser, giving rise to a sizably lower Raman signal. For this crystal, the parallel polarization measurements showed 9 of the total $10 \mathrm{~A}_{\mathrm{g}}$ modes. Using crossed polarization, $5 \mathrm{~B}_{\mathrm{gg}}$ modes were detected with $z$ incidence and $2 \mathrm{~B}_{2 \mathrm{~g}}$ modes, with $y$ incidence. In all cases, small leaked contributions to $\mathrm{A}_{\mathrm{g}}$ modes were found. Finally, all peaks from the polarized measurements were compared with those obtained from the powder sample, which allowed us to detect 2 extra modes belonging to the $\mathrm{B}_{3 \mathrm{~g}}$ symmetry. The total amount of detected zone-center modes for the Co vanadate is 18 modes of the 36 available. Seo et al. were able to measure 8 modes of this compound, ${ }^{54}$ obtaining similar frequency values compared with this work. All of these mode identifications are supported by ab initio computations, showing satisfactory experiment-simulation agreement. The ambient pressure wavelength values of the vibrational modes for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, along with the calculated and literature values, are shown in Table 4.
3.4. High-Pressure Raman Spectroscopy $\left(\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}\right.$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ ). In the present powder vibrational HP studies, 24 modes for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ are monitored up to 19.5(1) GPa and 14 modes for $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, up to 20.4(1) GPa, as shown for selected

Figure 8. Pressure dependence of the Raman modes of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. The symmetry modes are assigned with colors on the right, matching the end of the solid line in the figure.
spectra in Figures 6 and 7, respectively. Pressure coefficients under ambient conditions are presented in Table 4. The pressure coefficients were fitted using the spectra obtained near ambient conditions, where the dependence on pressure is linear. As found in previous HP XRD studies ${ }^{23}$ for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, this compound does not undergo any nonisostructural phase transition in the covered pressure range. Now, this statement can also be applied to $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$.
The pressure dependence of the calculated and experimentally measured phonon wavenumbers is shown in Figure 8 for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and in Figure 9 for $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. It can be seen that all of the observed modes, except the $\mathrm{A}_{\mathrm{g}}^{1}$ mode, upshift with increasing pressure. In $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, the $\mathrm{A}_{\mathrm{g}}^{8}$ and $\mathrm{B}_{3 \mathrm{~g}}^{9}$ modes were no longer differentiated out of the background because of signal attenuation as pressure increased. The experimental values of these coefficients are broadly in good agreement with those obtained in the ab initio calculations. The calculated lines in Figures 8 and 9 run parallel to the experimental points with the calculated lines generally shifted by less than $5 \%$ with respect to the measured data. Only a single crossover is observed experimentally between $\mathrm{B}_{2 \mathrm{~g}}^{6}$ and $\mathrm{A}_{\mathrm{g}}^{7}$ in $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, which is well reproduced by the DFT calculations. All data sets collected on decompression follow the same behavior as upstroke measurements. When comparing both orthovanadates, the first dissimilarity observed is that, in spite of the larger mass of Ni , all modes in $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ are slightly lower in wavelength (approximately $10 \mathrm{~cm}^{-1}$ ), while high-pressure events, such as the mode crossover, occur earlier in pressure for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ (see $\mathrm{A}_{\mathrm{g}}^{6}-\mathrm{B}_{1 \mathrm{~g}}^{7}, \mathrm{~A}_{\mathrm{g}}^{3}-\mathrm{B}_{1 \mathrm{~g}}^{4}$, or $\mathrm{A}_{\mathrm{g}}^{6}-\mathrm{B}_{3 \mathrm{~g}}^{7}$ in Figures 8 and 9).

Figure 9. Pressure dependence of the Raman modes of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. The symmetry modes are assigned with colors on the right, matching the end of the solid line in the figure.

These observations suggest that $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ behaves as a pressurized version of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$.
3.5. High-Pressure X-ray Diffraction $\left(\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}\right)$. Using the XRD patterns collected for powder $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ under HP, the orthorhombic structure (space group Cmca, number 64) was fitted from $0.0(1)$ to $20.0(1) \mathrm{GPa}$. Le Bail refinement ${ }^{55}$ results are shown in Figure 10 for selected pressures. The patterns shown correspond to positions of the DAC where there was no Cu signal. This compound does not exhibit any phase transition in the mentioned pressure region, as was also published for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. ${ }^{24}$

Subsequently, the pressure dependence of the unit-cell parameters and corresponding volume of the orthorhombic structure of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ is reported in Figure 11, using the results from the Le Bail fits ${ }^{55}$ and peak indexation with UNITCELL. ${ }^{56}$ At $10.5(1) \mathrm{GPa}$, a slight change in the evolution of all three unit-cell axes was noticed. This fact coincides with the end of the hydrostatic region of the ME pressure-transmitting media, ${ }^{27}$ which is probably the reason that the linear compressibility of each axis is reduced. This nonhydrostatic effect led us to report two separate equations of state (EOSs), one up to the hydrostatic limit of ME (9.3(1) GPa) and another up to the maximum pressure ( $20.0(1) \mathrm{GPa})$. Thus, the unit-cell volume was fitted using a third-order BirchMurnaghan EOS ${ }^{48}$ employing EosFit7 software. ${ }^{57}$ The third order of the EOS was determined from the Eulerian strainnormalized pressure dependence of the data. ${ }^{58}$ All EOS parameters are reported in Table 5, along with literature ones for other Kagomé-staircase orthovanadates. The unit-cell parameters obtained by DFT calculations differ from the

Figure 10. XRD patterns at selected pressures (black dots) of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. Le Bail fits and residuals are shown with blue and red lines, respectively. Ticks indicate the Bragg peaks for the corresponding structural phase. Pressures are indicated in the figure. The top trace corresponds to the last experiment made during decompression.
experimental parameters by approximately $1 \%$ in terms of absolute value. Furthermore, the bulk moduli obtained in the EOS for both calculations (129.2(7) GPa) and experiments up to $9.3(1) \mathrm{GPa}(127.4(4) \mathrm{GPa})$ are in good agreement. Comparing these results with the bulk modulus reported for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}{ }^{24}$ it can be noticed that Co orthovanadate is more compressible than Ni orthovanadate. For this comparison, the two bulk moduli obtained by a second order EOS and under hydrostatic conditions were used, whose values are 122(4) and 143(3) GPa for Co and Ni vanadates, respectively (see Table 5). This fact agrees with the observations reported in the HP Raman section (3.4), where it was concluded that $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ behaves as a pressurized version of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. Overall, Ni and Co vanadates show bulk moduli within the range of all other Kagomé-staircase orthovanadates, with $\mathrm{Mg}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ being the highest (152(4) GPa) ${ }^{23}$ and $\mathrm{Mn}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$, the lowest (106(3) $\mathrm{GPa})^{21}$ to date.
From the reported unit-cell parameters, the linear isothermal compressibility was calculated for all axes of the orthorhombic structure: $\kappa_{x}=\frac{1}{x}\left(\frac{\partial x}{\partial P}\right)_{T}$, where $x=a, b$, or $c$. The linear compressibilities obtained are $\kappa_{a}=2.73(15) \times 10^{-3} \mathrm{GPa}^{-1}, \kappa_{b}$ $=1.98(4) \times 10^{-3} \mathrm{GPa}^{-1}$, and $\kappa_{c}=2.29(14) \times 10^{-3} \mathrm{GPa}^{-1}$. The region used for the fits is from $0.0(1)$ to $9.3(1) \mathrm{GPa}$ to guarantee that only hydrostatic data are used. When these compressibilities are compared with the experimentally obtained ones for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}{ }^{23}$ and simulated for other orthovanadates, ${ }^{59}$ it can be clearly appreciated that they follow the same behavior followed for this family of compounds, but the $b$-axis of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ is slightly more compressible. Once

Figure 11. Pressure dependence of the unit-cell parameters (top) and volume (bottom) of $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. Black symbols represent experimental measurements, and red lines are DFT calculations. Full circles represent upward pressure, while empty triangles release pressure data. The solid black line and dashed black line are the BirchMurnaghan EOS fitting of the experimental unit-cell volume up to 9.7 and 20 GPa , respectively.
more, this can be related to the "compressed" structure of $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ indicated in Section 3.4, since the $b$-axis is mainly influenced by the layers of $\mathrm{CoO}_{6}$ octahedra (see Figure 1), which are more compressible than the $\mathrm{NiO}_{6}$ octahedra. The DFT-calculated change in bond distances within the covered pressure range can be seen in Figures S1 and S2 for both compounds.

## 4. CONCLUSIONS

High-pressure vibrational studies were performed for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ powders up to $19.5(1)$ and $20.4(1) \mathrm{GPa}$, respectively, and no phase transition was found. Polarized Raman and infrared measurements on single crystals were used to separate and identify the symmetry of the vibrational modes for both compounds under ambient conditions. Ab initio DFT calculations are reported to confirm the symmetry, ambient pressure wavenumber value, and pressure coefficients of all the experimental modes found ( 24 for $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ and 17 for $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ out of the 36 Raman active modes). Although both Ni and Co orthovanadates present a similar vibrational behavior under pressure, it is found that $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ exhibits a more compact version of the structure. HP angle dispersive

Table 5. EOS Parameters (Cell Volume per Formula Unit, Bulk Modulus, and Its First Derivative) for Reported Kagomé-Staircase Orthovanadates

| XRD HP experiments | $V_{0}\left(\AA^{3}\right)$ | $B_{0}$ <br> $(\mathrm{GPa})$ | $B_{0}{ }^{\prime}$ |
| :---: | :---: | :---: | :--- |
| $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ up to $9.3(1) \mathrm{GPa}$ | $575.6(3)$ | $127(3)$ | 2.8 (9) |
| (this work) | $575.9(2)$ | $122(4)$ | 4.0 (fixed) |
| $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ up to $20.0(1) \mathrm{GPa}$ | $576.3(8)$ | $106(7)$ | $9.7(1.3)$ |
| (this work) | $574.0(6)$ | $142(3)$ | 4.0 (fixed) |
| $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ up to 7.6(1) $\mathrm{GPa}^{24}$ | $555.7(2)$ | $139(3)$ | $4.4(3)$ |
|  | $555.3(2)$ | $143(3)$ | 4.0 (fixed) |
| $\mathrm{Mn}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ up to $12 \mathrm{GPa}^{21}$ | $623.4(2)$ | $116(3)$ | $2.6(5)$ |
|  | $624.5(5)$ | $106(3)$ | 4.0 (fixed) |
| $\mathrm{Zn}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ up to $15 \mathrm{GPa}^{22}$ | $585.0(4)$ | $115(2)$ | $5.1(6)$ |
|  | $585.1(1)$ | $120(2)$ | 4.0 (fixed) |
| $\mathrm{Mg}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ up to $17 \mathrm{GPa}^{23}$ | $576.15(3)$ | $141(3)$ | $5.9(8)$ |
|  | $576.15(3)$ | $152(4)$ | 4 (fixed) |
| $\mathrm{DFT}^{2}$ calculations | $\mathrm{V}_{0}\left(\AA^{3}\right)$ | $\mathrm{B}_{0}(\mathrm{GPa})$ | $\mathrm{B}_{0}{ }^{{ }^{3}}$ |
| $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$ (this work) | $565.6(3)$ | $129(7)$ | $3.7(4)$ |
|  | $565.9(6)$ | $126(6)$ | 4.0 (fixed) |
| $\mathrm{Ni}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}{ }^{59}$ | 527.9 | 171 | 4.5 |
| $\mathrm{Zn}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}{ }^{59}$ | 563.2 | 136 | 5.4 |
| $\mathrm{Mg}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}{ }^{59}$ | 539.7 | 146 | 4.4 |

powder XRD analysis up to 20.0(1) GPa was also performed for $\mathrm{Co}_{3} \mathrm{~V}_{2} \mathrm{O}_{8}$. Anisotropic compressibility and EOS parameters (including bulk moduli) are obtained from both the experimental results and the DFT calculations. Excellent agreement is found between the two sets of data.
