Project Summary The project aims at defining the molecular mechanisms of Abeta- and Tau-induced synaptotoxicity and at developing disease-modifying therapeutics for the prevention of memory loss in Alzheimer disease (AD). This disease, an incurable brain disorder and the major contributor to dementia, is characterized by insoluble aggregates in the brain of affected individuals formed by Abeta peptides and the microtubule-binding protein Tau. Recent data suggest that Abeta aggregation precedes and triggers Tau pathology. One of the early and characteristic symptoms in AD is memory loss. Several lines of evidence suggest that the onset of memory decline does not require neuronal loss, is independent of plaques and tangles and is due to subtle and transient changes at the level of synapses. The toxic Abeta and Tau species that cause synaptic dysfunction, their mechanism of toxicity and the link between both pathologies remain largely unknown. In the past three years we employed primary neuronal cultures and animal models (*C.elegans*, zebrafish, and mouse) to define the pathologic pathways leading from Abeta through Tau to synaptotoxicity. In a first set of experiments, we investigated the effect of defined Abeta species on long-term potentiation, synaptic morphology, gene expression, Tau phosphorylation and aggregation, axonal transport, and behaviour. Similarly, we investigated the functional consequences of Tau malfunction, aggregation, hyperphosphorylation, and missorting in various cell culture systems (retinal ganglion cells, primary hippocampal neurons, organotypical slices) and animal models, especially with regard to intraneuronal traffic and synaptic function. Once the toxic Abeta and Tau species and their mechanism of toxicity had been defined, we investigated how these pathways interact. Unravelling the pathologic pathways that lead from Abeta through Tau to synaptotoxicity and memory loss should reveal novel points for therapeutic intervention.
