Abstract

Lactobacillus plantarum is a lactic acid bacteria that can be found in numerous fermented foods. Esterases from L. plantarum exert a fundamental role in food aroma. In the present study, the gene lp_2631 encoding a putative esterase was cloned and expressed in Escherichia coli BL21 (DE3) and the overproduced Lp_2631 protein has been biochemically characterized. Lp_2631 exhibited optimal esterase activity at 20 °C and more than 90% of maximal activity at 5 °C, being the first cold-active esterase described in a lactic acid bacteria. Lp_2631 exhibited 40% of its maximal activity after 2h incubation at 65 °C. Lp_2631 also showed marked activity in the presence of compounds commonly found in food fermentations, such as NaCl, ethanol, or lactic acid. The results suggest that Lp_2631 might be a useful esterase to be used in food fermentations.

KEYWORDS: Esterase, Food fermentation, Aroma, Esters, Lactic acid bacteria
INTRODUCTION

In fermented foods, microorganisms are in contact with food substrates, and their metabolic activities influence food aroma. Esters are important in determining the aroma, and, by extension, the quality of foods. These compounds are formed when alcohol and carboxylic acid functional groups react, and a water molecule is eliminated. Enzymatic ester synthesis and hydrolysis are catalyzed by esterases. Since lactic acid bacteria (LAB) are extensively used for the fermentation of food products, LAB esterases could influence the aroma of these fermented products. Among LAB, *Lactobacillus plantarum* is an industrially important species which can be found in numerous fermented foods, such as sourdoughs, olives, vegetables, sausages, cheese, and wine. *L. plantarum* is a good source of esterase enzymes since lipolytic and esterase activity have been previously described in *L. plantarum* strains. Although esterases or lipases are common in *L. plantarum*, so far only few have been partially purified, purified or recombinantly produced. These *L. plantarum* proteins exhibited different esterase activities and biochemical properties, such as lipases, acetyl esterases, or feruloyl esterase. So far, all the esterases described in *L. plantarum* exhibited optimal temperature for activity around 30-40 ºC. However, the role of *L. plantarum* in aroma development could be important when optimal activity conditions are close to those found in meat, milk or wine fermentations. During these fermentations temperatures as low as 15 ºC are found. For most of the enzymes, lowering the temperature by 10 ºC decreases the rate of reaction by two to three fold. Currently, cold-adapted esterases have emerged as one of the most promising biocatalysts because, when compared with mesophilic or thermophilic enzymes, they display a much higher catalytic efficiency at a low or moderate temperature. This feature can meet the demands of some industrial applications, including additives in food.
processes (fermentation, cheese manufacture, bakery, meat tenderizing). So far, only a few cold-adapted esterases have been discovered and characterized, none of them from LAB.

As *L. plantarum* is a mesophilic organism which would often encounter temperatures below 20 °C in nature or in food fermentations, it seems likely that it would be a good source for enzymes with interesting novel properties, e.g., enzymes active in cold conditions. The genome sequence of *L. plantarum* WCFS1 was published in 2003 and more than twenty putative esterase or lipase genes were annotated on the basis of similarity searches. Although an operational distinction is made between esterases, which preferentially break the ester bonds of shorter chain acyl substrates at least partly soluble in water, and lipases, which display maximal activity toward water-insoluble long-chain triglycerides, there is no fundamental biochemical difference. Both esterases and lipases are members of the α/β hydrolase superfamily, and share the same catalytic mechanisms for ester hydrolysis and formation. Classifications based on sequence similarities do not separate the two classes of enzymes.

This study presents an effort to elucidate the ester hydrolysis activities in *L. plantarum* whole cells by cloning, heterologous expression, purifying and characterizing the esterase Lp_2631 from *L. plantarum*. Esterase Lp_2631 is the first cold-active esterase described in LAB species used in food fermentations. With a view to applying Lp_2631 cold-active esterase under fermentation conditions, enzyme activity in the presence of compounds commonly found in food fermentations was examined.

**MATERIALS AND METHODS**
Strains, plasmids, media and materials. *L. plantarum* WCFS1, kindly provided by M. Kleerebezem (NIZO Food Research, The Netherlands), was grown in MRS medium (Pronadisa, Spain) adjusted to pH 6.5 and incubated at 30 °C. This strain is a colony isolate of *L. plantarum* NCIMB 8826, which was isolated from human saliva. *Escherichia coli* DH10B was used as host strain for all DNA manipulations. *E. coli* BL21 (DE3) was used for heterologous expression in the pURI3-TEV vector. E. coli strains were cultured in Luria-Bertani (LB) medium at 37 °C and shaking at 200 rpm. When required, ampicillin and chloramphenicol were added to the medium at a concentration of 100 or 20 μg/mL, respectively.

Plasmid DNA was extracted by a High Pure plasmid isolation kit (Roche). PCR product was purified with a QIAquick gel extraction kit (Qiagen). Oligonucleotides were purchased from Eurofins MWG Operon (Ebersberg, Germany). *Dpn*I and HS Prime Star DNA polymerase were obtained from TaKaRa. Histagged protein was purified by a Talon Superflow resin (Clontech).

Cloning of Lp_2631 esterase encoding gene. Genomic DNA from *L. plantarum* WCFS1 was extracted. The gene encoding a putative lipase/esterase (*lp_2631*) in *L. plantarum* WCFS1 was amplified by PCR by using the primers 569 (5´-GGTGAAAACCTGTATTTCCAGGCatgtgcggacgaccaaatttggtg) and 570 (5´-ATCGATAAGCTTAGTTAGCTATTAttaagaatggtgctccaag) (the nucleotides pairing the expression vector sequence are indicated in italics, and the nucleotides pairing the *lp_2631* gene sequence are written in lowercase letters). Prime Star HS DNA polymerase (TaKaRa) was used for the PCR amplification. The 786-bp purified PCR product was inserted into the pURI3-TEV vector using a restriction enzyme- and ligation-free cloning strategy. The vector produces recombinant proteins having a six-histidine affinity tag in
their N-termini. *E. coli* DH10B cells were transformed, recombinant plasmids were isolated, and those containing the correct insert were identified by size, verified by DNA sequencing, and then transformed into *E. coli* BL21 (DE3) cells for expression.

**Expression and purification of Lp_2631 esterase.** *E. coli* BL21(DE3) harbouring pGro7 (TaKaRa), a vector overexpressing GroES/GroEL chaperones, was transformed with the recombinant plasmid pURI3-TEV2631. *E. coli* was grown in LB medium containing 100 \( \mu \)g/mL ampicillin, 20 \( \mu \)g/mL chloramphenicol, and 2 mg/mL arabinose, on a rotary shaker (200 rpm) at 37 °C until an optical density (OD) at 600 nm of 0.4 was reached. Isopropyl-\( \beta \)-D-thiogalactopyranoside (IPTG) was added to a final concentration of 0.4 mM and protein induction was continued at 22 °C during 18 h.

The induced cells were harvested by centrifugation (8,000 g, 15 min, 4 °C), resuspended in phosphate buffer (50 mM, pH 7) containing 300 mM NaCl and disrupted by French Press passages (three times at 1,100 psi). The insoluble fraction of the lysate was removed by centrifugation at 47,000 g for 30 min at 4 °C, and the supernatant was filtered through a 0.2 \( \mu \)m pore-size filter and then loaded onto a Talon Superflow resin (Clontech) equilibrated in phosphate buffer (50 mM, pH 7) containing 300 mM NaCl and 10 mM imidazole to improve the interaction specificity in the affinity chromatography step. The bound enzyme was eluted using McIlvaine buffer (100 mM, pH 5). The purity of the enzyme was determined by SDS-PAGE in Tris-glycine buffer. Fractions containing the His6-tagged protein were pooled and analyzed for esterase activity.

**Enzyme assay.** Esterase activity was determined by a spectrophotometric method as described previously using \( p \)-nitrophenyl acetate (Sigma-Aldrich) as the substrate.
Substrate specificity. To investigate the substrate specificity of Lp_2631, activity was determined using different p-nitrophenyl esters of various chain lengths (Sigma-Aldrich): p-nitrophenyl acetate (C2), p-nitrophenyl butyrate (C4), p-nitrophenyl caprylate (C8), p-nitrophenyl laurate (C12), p-nitrophenyl myristate (C14) and p-nitrophenyl palmitate (C16) as substrates as described previously. 18, 23

Determination of optimum pH, temperature and thermostability. Effect of pH was studied by assaying esterase activity in a range of pH values from 3.0 to 9.0 as described previously. 18 Temperature effect was assayed in 50 mM sodium phosphate buffer (pH 7.0) at 5, 20, 30, 37, 40, 45, 55, and 65 ºC for 10 min. For temperature stability measurements, the esterase was incubated in 50 mM sodium phosphate buffer (pH 7.0) at 22, 30, 37, 45, 55 and 65 ºC for 5 min, 15 min, 30 min, and 1, 2, 4, 6, and 20 h. After incubation, the residual activity was measured as described above.

Effects of additives on Lp_2631 esterase activity. The effect of metals ions, surfactants, reductants, and inhibitors on the activity of the esterase was assayed by incubation of the enzyme in the presence of different additives at a final concentration of 1 mM during 5 min at room temperature. Then, the substrate was added and the reaction was incubated at 20 ºC. 18 The compounds analyzed were MgCl$_2$, KCl, MnCl$_2$, CuCl$_2$, NiCl$_2$, CaCl$_2$, HgCl$_2$, ZnCl$_2$, diethylpyrocarbonate (DEPC), Cysteine, SDS, DTT, Triton-X-100, Urea, Tween 80, Tween 20, ethylenediamine tetracetic acid (EDTA), dimethyl sulfoxide (DMSO), phenylmethanesulfonyl fluoride (PMSF) and β-mercaptoethanol.

In addition, the effect of several compounds present in food fermentation was assayed. The effect of ethanol on esterase activity was studied at ethanol concentrations ranging from 0 to 20% (vol/vol). Reaction mixtures were prepared as described for the
temperature optimum experiments, but different volumes of ethanol were added, and the volume of the buffer was adjusted accordingly to maintain the final reaction volume (1 mL). The reactions were pre-incubated 5 min at room temperature, and the substrate (p-nitrophenyl acetate) was added. The effect of the presence of several organic acids was also studied. Malic, tartaric, citric, and lactic acids were assayed at concentrations ranging from 0 to 5 g/L. Reaction mixtures were prepared by adding different volumes of the corresponding stock solution (25 g/L) prepared in phosphate buffer (50 mM, pH 7.0). The effect of sulfite was determined by adding sodium metabisulfite at concentrations ranging from 0 to 1 g/L. The reactions were done by adding different volumes of a 25 g/L stock solution. Finally, the effect of NaCl was determined by adding NaCl at concentrations ranging from 0 to 25% (vol/vol). Reaction mixtures were prepared as described for the temperature optimum experiments, but different volumes of 25% NaCl solution were added, and the volume of the buffer was adjusted accordingly to maintain the final reaction volume. Reactions mixtures were pre-incubated for 5 min at room temperature before the enzyme was added. After the reaction, the absorbance was measured at 348 nm.

Statistical analyses. The two-tailed Student’s t test performed using GraphPad InStat version 3.0 (GraphPad Software, San Diego, CA), was used to determine the differences between means. The data are representative means of at least three independent experiments.

RESULTS AND DISCUSSION

Production and characterization of Lp_2631 esterase. LAB are used for the preservation of food raw materials such as milk, meat, and vegetable or other plant
materials. *L. plantarum* is a flexible and versatile species that is encountered in a variety of environmental niches, including some dairy, meat, and many vegetable or plant fermentations. The ecological flexibility of *L. plantarum* is reflected by the observation that this species has one of the largest genomes known among LAB.\textsuperscript{10} This large genome codifies enzymatic activities which could develop a fundamental role in food fermentations, such as cold-active esterases (also known as cold-adapted). When the published sequence of *L. plantarum* WCFS1 was analyzed, numerous ORFs encoding putative esterases/lipases were found. As it is not possible predict the biochemical function encoded by these *L. plantarum* ORFs, features found in cold-active esterases were searched. According to previous studies,\textsuperscript{24-26} compared with mesophilic or themophilic esterases, cold-adapted enzymes revealed structural traits, such as a low ratio or Arg/(Arg+Lys), a low proportion of proline residues, or a high proportion of small residues (Gly and Ala). Among the putative esterases encoded by the *L. plantarum* WCFS1 genome, *lp*\_\textsubscript{2631} encodes a protein that exhibits some of these structural features. Thus, when the amino acid composition of Lp\_2631 was analyzed, the ratio of Arg/(Arg+Lys) was found to be 0.45, lower than that of other cold-adapted esterases: 0.50 in Est10 from *Psychrobacter pacificensis*,\textsuperscript{27} or 0.56 in rES\textsubscript{97} from a metagenomic library.\textsuperscript{28} Also the total percentage (20.31\%) of small residues Gly (7.28\%) and Ala (13.03\%) is relatively high compared with the low proportion of Arg (3.45\%) and Pro (5.75\%). These characteristics of the primary structure may suggest that Lp\_2631 could be a cold-active esterase.

Lp\_2631 is predicted to encode a 261 amino acid protein 42\% identical to a putative esterase/lipase from *Lactobacillus sakei*, and 35\% identical to uncharacterized proteins from *Lactobacillus salivarius* or *Lactobacillus ruminis* (data not shown).
The \textit{lp}_2631\ gene was cloned into the pURI3-TEV expression vector and the
recombinant plasmid obtained was transformed into \textit{E. coli} BL21 (DE3). Cell extracts
were used to detect the presence of overproduced proteins. SDS-PAGE analysis showed
that there was one major band of protein, approximately 28 kDa, present as inclusion
bodies in the insoluble fraction. In order to get \textit{Lp}_2631 soluble, plasmid pGro7,
producing GroES/GroEL chaperones, was used. When pURI3-TEV-2631 and pGro7
plasmids were used simultaneously, \textit{Lp}_2631 appeared in the intracellular soluble fraction
of the cells (Figure 1). The molecular weight of the overproduced protein was consistent
with the theoretical one expected for \textit{Lp}_2631. The recombinant protein was observed as
single band on SDS-PAGE (Figure 1). Routinely about 8 mg of purified protein from 1-
liter culture was obtained.

\textit{Lp}_2631 protein purified by the affinity resin was biochemically characterized.
Substrate specificity was determined using \textit{p}-nitrophenyl-linked esters of various acyl
chain lengths (C2 to C16) at 20 °C (Figure 2). The enzyme was only active on substrates
with a chain length up to C4, with minimal activity detected with the longer chain lengths.
This result indicated that \textit{Lp}_2631 is an esterase and not a true lipase. This narrow
substrate range displayed by \textit{Lp}_2631 is similar to the substrate range described for a \textit{L.}
\textit{plantarum} esterase described previously.\textsuperscript{23}

The influence of pH, in the range 3.0 to 9.0, on esterase activity was studied at 20
°C (Figure 3A). Although the enzyme showed activity at pH from 3.0 to 8.0, the highest
activity was observed at pH 6.5. Similarly to the substrate range, only the esterase
described previously by Brod et al (2010) exhibited an optimal pH range of 6.0-6.5. Apart
from these both esterases, the \textit{L. plantarum} esterases described so far showed higher
optimum pH, 7 for \textit{Lp}_2923\textsuperscript{29} and a feruloyl esterase,\textsuperscript{18} and pH 8 for \textit{Lp}_0796.\textsuperscript{30} LAB
fermented food products are characterized by a low pH. For example, a final pH around
5.5 could be found in meat fermentations; at this pH, Lp_2631 still exhibited 40% of its maximal activity.

The influence of temperature on enzymatic activity was determined (Figure 3B). Maximal activity was observed at 20 ºC, confirming previous structural data of Lp_2631 suggesting that this esterase could be a cold-adapted protein. As far as we know, Lp_2631 is the first esterase from *L. plantarum* exhibiting such functional features. In fact, other *L. plantarum* esterases show higher optimal temperatures, such as 30 ºC for Lp_2923, 30 ºC for Lp_0796, or 40 ºC for Lp_0973. More interestingly, Lp_2631 showed more than 90% activity at 5 ºC, and decreases to 30% at 30 ºC. Similar behaviour has been described in cold-active esterases described from non-LAB or metagenomic libraries. Lp_2631 is the first esterase described from LAB which shows higher activity at refrigeration temperatures. This is an important property in food fermentations; e. g., during the ripening of a fermented meat product in the traditional manufacturing process, temperatures can be as low as 15 ºC; moreover esterase activity could be important even at meat storage temperatures (3 ºC, 7.5 ºC).

The available data regarding psychrophilic enzymes pointed out that the high specific activity at low temperatures is often associated to a low thermostability, which make them inclined to loose their activity at moderate and even high temperature. Low temperature activity has been generally associated with low conformational stability. In order to assess the thermostability of Lp_2631, the enzyme was preincubated at different temperatures for different time intervals, before assaying the residual activity. Figure 3C shows that Lp_2631 was fairly stable under room temperatures. The enzyme retained up to 80% activity after incubation during 20 h at 20 ºC. The enzyme showed 50% of its maximal activity after 4 h incubation at 30 or 37 ºC, or 40% after 2 h at 45 to 65 ºC. Therefore, esterase Lp_2631 not only showed high activity levels at low temperature, but
also exhibited higher thermostability when compared with other cold-active enzymes, e.g., the low-temperature lipase from psychrotopic *Pseudomonas* sp. strain KB700A. In fact, other cold-adapted esterases are also fairly stables. Although high catalytic activity at low temperature tends to be associated with thermosensitivity, directed evolution studies to improve the thermostability of cold-adapted enzymes revealed that, as in Lp_2631, there is not a strict correlation.

The effects of several ions, surfactants, reductants, and inhibitors on Lp_2631 activity are shown in Figure 4. Compared to the enzyme incubated in 50 mM phosphate buffer pH 7, the enzymatic activity was increased two-fold by the detergents Tween-20 and Tween-80, and, by contrast, SDS greatly inhibited Lp_2631. The increase in enzyme activity observed by non-ionic detergents, and the decrease by ionic detergent was previously described in a feruloyl esterase from *L. plantarum* and in the cold-active lipase EML1 from a deep-sea sediment metagenome. Regarding to metal ions, only Mn$^{2+}$ increases activity, while Ni$^{2+}$, Cu$^{2+}$, and Hg$^{2+}$ significantly inhibited esterase activity. Inactivation by Hg$^{2+}$ ions has been previously described in other *L. plantarum* esterases, such a feruloyl esterase and a lipase purified from *L. plantarum* 2739. Normally, the esterase activity of hydrolases does not require cofactors such as metals. On the contrary, the inhibitory effects of some of them are observed and explained in terms of covalent modification of catalytic residues (such as the covalent modification of thiol groups by Hg$^{2+}$). The effects of other metals on esterase activity (either activating or inhibiting the enzyme) have also been reported; however, the molecular mechanisms underlying these effects have not been determined and most probably they are unspecific. The enzyme was also partially inactivated by PMSF and DEPC confirming the involvement of a serine and a histidine at the active site of the enzyme.
Activity of Lp_2631 in the presence of compounds found in food fermentations. Also important, in order to understand the role of Lp_2631 esterase activity during food processing, is the study of compounds present in food fermentation media that could affect its activity. Food processing subjects microorganisms, and their enzymes, to adverse environmental conditions (such as osmotic stress, toxic compounds, ethanol), which affect their survival and technological performances. Because of its industrial relevance, a better understanding of the influence of compounds present in food fermentations is important. The influence on Lp_2631 activity of several compounds naturally present in food fermentations such as ethanol, malic acid, tartaric acid, and sodium metabisulfite in winemaking, NaCl in cheese and meat fermentations, and lactic acid as a main product resulting for LAB fermentation was also studied.

Ethanol concentration is an important compound during winemaking, because malolactic fermentation is often conducted after the completion of alcoholic fermentation, when ethanol concentration of wine can exceed 12%. For this reason, the influence of ethanol on the Lp_2631 esterase activity has been analyzed. Experiments were conducted with concentrations higher than those found in wines (up to 20%). The highest esterase activity was observed in absence of ethanol, however, at wine ethanol concentrations (12%), Lp_2631 exhibited a 40% of its maximal activity (Figure 5A). A different ethanol effect was observed in an esterase from the wine bacterium O. oeni since it was stimulated by 14% ethanol, producing a 49% activity increase.

In addition, sodium metabisulfite, a powerful antimicrobial commonly used in wine, did not inhibit the enzyme when present at concentrations commonly found in wine. Final levels of 0.1 to 0.2 g/L of metabisulfite are found in wines. At wine concentrations, metabisulfite increases up to 70% esterase activity (Figure 5B). Again, Lp_2631 esterase showed a different behaviour than O. oeni esterase which was partially inhibited in
presence of metabisulfite. In grape must there are several organic acids, such as malic acid (up to 8.6 g/L), or tartaric acid (up to 7.4 g/L). During vinification the concentration of these acids varies, and as a consequence of LAB metabolism, lactic acid appeared. In wines, concentrations of 5, 4 and 4 g/L of malic, tartaric or lactic acid, respectively, could be found. Esterase Lp_2631 showed activity at wine concentrations of these organic acids. Malic acid concentrations up to 5 g/L increased esterase activity (Figure 5C); however, esterase was partially inhibited by tartaric and lactic acid at wine concentrations (Figure 5D and 5E). Lp_2631 activity was not affected by concentrations of citric acid usually found in grape musts or wines, maximum 0.90 and 0.88 g/L, respectively. L. plantarum strains are active in fermented foods, such as milk or meat fermentations, in which salt, citric or lactic acid are present. Under cheese ripening conditions (4% NaCl), Lp_2631 was only partially inhibited, retained 74% of its maximal activity at 5% (Figure 5G). Citric and lactic acid showed a similar behaviour, both acids inhibited Lp_2631 activity at 5 g/L, whereas at 1 g/L the enzyme keeps full activity. At cheese concentrations (50 mg/100 g), citric acid did not inhibit Lp_2631 activity. The activity showed by Lp_2631 suggests that this esterase could play a role in modulating ester profiles during cheese ripening.

The obtained results indicated that Lp_2631 is an esterase which retains activity under conditions commonly found in food fermentations, such as cold temperature, the presence of salt, ethanol, organic acids, or antimicrobials. The main disadvantage for the use of Lp_2631 in food fermentations is its narrow pH profile under standard reaction conditions. Further assays need to be done under combined conditions in order to known the effect of the simultaneous presence of different factors on Lp_2631 activity.
In conclusion, in the present study the cold-active esterase namely Lp_2631 from L. plantarum, an industrially important LAB species which can be found in numerous fermented foods, was purified and biochemically characterized. Lp_2631 is a cold-active esterase that exhibited maximum activity at 20 °C, and more importantly, retains more than 90% activity at refrigeration temperatures. In addition, esterase Lp_2631 not only showed a good activity at low temperatures, but also had good thermostability compared with other cold-active enzymes. Based on the findings reported in this study, it appears that Lp_2631 will retain adequate activity under food fermentation conditions.
