(Received 17 November 2008; published 6 January 2009)

We analyze the entanglement dynamics of a system composed by a pair of neutral two-level atoms that are initially entangled, and the electromagnetic field, initially in the vacuum state, within the formalism of perturbative quantum field theory up to the second order. We show that entanglement sudden death and revival can occur while the atoms remain spacelike separated and therefore cannot be related with photon exchange between the atoms. We interpret these phenomena as the consequence of a transfer of atom-atom entanglement to atom-field entanglement and vice versa. We also consider the different bipartitions of the system, finding similar relationships between their entanglement evolutions.

I. INTRODUCTION

Entanglement between qubits may disappear in a finite time when the qubits interact with a reservoir. This is commonly known as “entanglement sudden death” (ESD). After its discovery [1–3], the phenomenon has attracted great attention (for instance, [4–12]) and has been observed experimentally [13].

ESD shows up in a variety of systems that can be roughly divided in two sets: Those in which the qubits interact individually with different reservoirs and those in which they interact with a common environment. In particular, in [6,7,14] a system of a pair of two-level atoms interacting with a common electromagnetic vacuum is considered. The dynamics of the system is given in all the cases by the Lehmberg-Agarwal master equation [15,16] which is derived with the rotating wave approximation (RWA) and the Born-Markov approximation. Recently, non-Markovian [8] and non-RWA [17] effects have been considered in systems of qubits coupled individually to different reservoirs. There are good reasons for going beyond the Markovian and RWA scenario in the case of a pair of two-level atoms in the electromagnetic vacuum. For short enough times non-RWA contributions are relevant [18] and a proper analysis of causality issues can only be performed if they are taken into account [19–21]. Besides, as we shall show in this paper the death of the entanglement between the atoms is related with the birth of entanglement between the atoms and the field, and therefore the field is actually a non-Markovian reservoir. This was also the case in [5,10,11] with different reservoirs.

In [18,22,23] we have applied the formalism of perturbative quantum electrodynamics (QED) to the system of a pair of neutral two-level atoms interacting locally with the electromagnetic field, and for initially separable states analyzed the generation of entanglement. This is a non-Markovian, non-RWA approach. The use of the Lehmberg-Agarwal master equation can be seen as coarse grained in time approxi-

mation to the perturbative treatment [24]. The first goal of this paper is to apply also the QED formalism to analyze the ESD in these systems for initially entangled atomic states, comparing the results with the previously obtained [6,7] with master equations. We will focus mainly on the range $r/(ct) \approx 1$, r being the interatomic distance and t the interaction time, in order to investigate the role of locality. We will also consider these systems for the rest of the pairwise concurrences, namely the entanglement of each atom with the field, and multipartite entanglement, following the spirit of [5,10–12]. While the mentioned papers deal with a four-qubit model, our model here consists in two qubits (the atoms) and a qutrit (the electromagnetic field, which may have zero, one or two photons). We shall show that the phenomenon of revival of entanglement after the ESD [7] can occur for $r > ct$, and therefore is not related with photon exchange as is usually believed. We will see that atom-atom disentanglement is connected with the growth of atom-field entanglement and vice versa. Similar relationship will be obtained among the “atom-(atom+field)” and “field-(atom+atom)” entanglements.

The reminder of the paper is organized as follows. In Sec. II we will describe the Hamiltonian and the time evolution from the initial state of the system. In Sec. III we will obtain the reduced state of the atoms and analyze the behavior of its entanglement. In Sec. IV the same will be performed with the reduced state of each atom and the field, comparing the entanglement cycle with the one obtained in the preceding section. Tripartite entanglement will be considered in Sec. V in terms of the entanglement of all the different bipartitions of the system, and we conclude in Sec. VI with a summary of our results.

II. HAMILTONIAN AND STATE EVOLUTION

To address the atom-field interactions, we assume that the relevant wavelengths and the interatomic separation are much larger than the atomic dimensions. The dipole approximation, appropriate to these conditions, permits the splitting of the system Hamiltonian into two parts $H = H_0 + H_I$ that are separately gauge invariant. The first part is the Hamiltonian in the absence of interactions other than the potentials that keep A and B stable, $H_0 = H_A + H_B + H_{\text{field}}$. The second con-

^{*}leon@imaff.cfmac.csic.es; <http://www.imaff.csic.es/pcc/QUINFOG/>

[†]cs1@imaff.cfmac.csic.es; <http://www.imaff.csic.es/pcc/QUINFOG/>

tains all the interaction of the atoms with the field, which in the dipole approximation we will use is given by

$$H_I = -\frac{1}{\epsilon_0} \sum_{n=A,B} \mathbf{d}_n(\mathbf{x}_n, t) \mathbf{D}(\mathbf{x}_n, t), \quad (1)$$

where $\mathbf{D}$ is the electric displacement field, and $\mathbf{d}_n = \sum_i e \int d^3 \mathbf{x}_i \langle E | (\mathbf{x}_i - \mathbf{x}_n) | G \rangle$ is the electric dipole moment of atom n , that we will take of equal magnitude for both atoms ($\mathbf{d} = \mathbf{d}_A = \mathbf{d}_B$) as required by angular momentum conservation in the photon exchange. $|E\rangle$ and $|G\rangle$ will denote the excited and ground states of the atoms, respectively.

In what follows we choose a system given initially by an atomic entangled state, with the field in the vacuum state $|0\rangle$,

$$|\psi\rangle_0 = (\alpha |EE\rangle + \beta |GG\rangle) |0\rangle. \quad (2)$$

The system then evolves under the effect of the interaction during a lapse of time t into a state

$$|\psi\rangle_t = T(e^{-i \int_0^t dt' H_I(t')/\hbar}) |\psi\rangle_0, \quad (3)$$

T being the time ordering operator. Up to second order in perturbation theory, (3) can be given in the interaction picture as

$$|\text{atom1, atom2, field}\rangle_t = \alpha |EE0\rangle_t + \beta |GG0\rangle_t, \quad (4)$$

where

$$|EE0\rangle_t = ((1+a)|EE\rangle + b|GG\rangle)|0\rangle + (u_A|GE\rangle + u_B|EG\rangle)|1\rangle + (f|EE\rangle + g|GG\rangle)|2\rangle \quad (5)$$

and

$$|GG0\rangle_t = ((1+a')|GG\rangle + b'|EE\rangle)|0\rangle + (v_A|EG\rangle + v_B|GE\rangle)|1\rangle + (f'|GG\rangle + g'|EE\rangle)|2\rangle, \quad (6)$$

where

$$a = \frac{1}{2} \theta(t_1 - t_2) \langle 0 | \mathcal{S}_A^+(t_1) \mathcal{S}_A^-(t_2) + \mathcal{S}_B^+(t_1) \mathcal{S}_B^-(t_2) | 0 \rangle,$$

$$a' = \frac{1}{2} \theta(t_1 - t_2) \langle 0 | \mathcal{S}_A^-(t_1) \mathcal{S}_A^+(t_2) + \mathcal{S}_B^-(t_1) \mathcal{S}_B^+(t_2) | 0 \rangle,$$

$$b = \langle 0 | T(\mathcal{S}_B^- \mathcal{S}_A^-) | 0 \rangle, \quad b' = \langle 0 | T(\mathcal{S}_B^+ \mathcal{S}_A^+) | 0 \rangle,$$

$$u_A = \langle 1 | \mathcal{S}_A^- | 0 \rangle, \quad v_A = \langle 1 | \mathcal{S}_A^+ | 0 \rangle,$$

$$u_B = \langle 1 | \mathcal{S}_B^- | 0 \rangle, \quad v_B = \langle 1 | \mathcal{S}_B^+ | 0 \rangle,$$

$$f = \frac{1}{2} \theta(t_1 - t_2) \langle 2 | \mathcal{S}_A^+(t_1) \mathcal{S}_A^-(t_2) + \mathcal{S}_B^+(t_1) \mathcal{S}_B^-(t_2) | 0 \rangle,$$

$$f' = \frac{1}{2} \theta(t_1 - t_2) \langle 2 | \mathcal{S}_A^-(t_1) \mathcal{S}_A^+(t_2) + \mathcal{S}_B^-(t_1) \mathcal{S}_B^+(t_2) | 0 \rangle,$$

$$g = \langle 2 | T(\mathcal{S}_B^- \mathcal{S}_A^-) | 0 \rangle, \quad g' = \langle 2 | T(\mathcal{S}_B^+ \mathcal{S}_A^+) | 0 \rangle \quad (7)$$

being $\mathcal{S} = -\frac{i}{\hbar} \int_0^t dt' H_I(t') = \mathcal{S}^+ + \mathcal{S}^-$, T the time ordering operator and $|n\rangle, n=0,1,2$ is a shorthand for the state of n photons with definite momenta and polarizations, i.e., $|1\rangle = |\mathbf{k}, \epsilon\rangle$, etc. Here, a and a' describe intra-atomic radiative corrections, u_A (u_B) and v_A (v_B) single photon emission by atom A (B), and

g and g' by both atoms, while f and f' correspond to two photon emission by a single atom. Only b and b' correspond to interaction between both atoms. The sign of the superscripts is associated to the energy difference between the initial and final atomic states of each emission or absorption. In quantum optics, virtual terms like a' , b , b' , v_A , v_B , f , f' , and g' , which do not conserve energy and appear only at very short times, are usually neglected by the introduction of a RWA. In the dipole approximation the actions $\hbar \mathcal{S}^\pm$ in (5) reduce to

$$\mathcal{S}^\pm = \frac{i}{\hbar} \int_0^t dt' e^{\pm i \Omega t'} \mathbf{d} E(\mathbf{x}, t'), \quad (8)$$

where $\Omega = \omega_E - \omega_G$ is the transition frequency, and we are neglecting atomic recoil. This depends on the atomic properties Ω and $\mathbf{d}$, and on the interaction time t . In our calculations we will take $(\Omega |\mathbf{d}| / ec) = 5 \times 10^{-3}$, which is of the same order as the $1s \rightarrow 2p$ transition in the hydrogen atom, consider $\Omega t \approx 1$, and focus mainly on the cases $(r/ct) \approx 1$. Therefore, $|E\rangle$ is actually a triply degenerate state $|E, m\rangle$ with $m=0, \pm 1$ and we will average over two different independent possibilities for dipole orientations: $\mathbf{d}_A = \mathbf{d}_B = \mathbf{d} = d \mathbf{u}_z$ for transitions with $\Delta m=0$ [25] and $\mathbf{d} = d(\mathbf{u}_x \pm i \mathbf{u}_y) / \sqrt{2}$ [25] for transitions with $\Delta m = \pm 1$.

III. SUDDEN DEATH AND REVIVAL OF ATOM-ATOM ENTANGLEMENT

After tracing over all the states of the field, the density matrix of the atomic state ρ_{AB} takes the form (in the basis $\{|EE\rangle, |EG\rangle, |GE\rangle, |GG\rangle\}$)

$$\rho_{AB} = \frac{1}{N} \begin{pmatrix} \rho_{11} & 0 & 0 & \rho_{14} \\ 0 & \rho_{22} & \rho_{23} & 0 \\ 0 & \rho_{23}^* & \rho_{33} & 0 \\ \rho_{14}^* & 0 & 0 & \rho_{44} \end{pmatrix}, \quad (9)$$

where

$$\rho_{11} = |\alpha(1+a) + \beta b'|^2 + |\alpha f + \beta g'|^2,$$

$$\rho_{22} = \rho_{33} = |\alpha|^2 |u|^2 + |\beta|^2 |v|^2 + 2 \text{Re}(\alpha \beta^* l^*),$$

$$\rho_{44} = |\alpha b + \beta(1+a')|^2 + |\alpha g + \beta f'|^2,$$

$$\rho_{14} = |\alpha|^2 [(1+a)b^* + fg^*] + |\beta|^2 [(1+a')^* b' + g' f'^*] + \alpha \beta^* [(1+a)(1+a') + ff'^*] + \beta \alpha^* (b' b^* + g' g^*),$$

$$\rho_{23} = |\alpha|^2 u_B u_A^* + |\beta|^2 v_A v_B^* + 2 \text{Re}(\alpha \beta^* uv^*),$$

$$N = \rho_{11} + \rho_{22} + \rho_{33} + \rho_{44}, \quad (10)$$

where $|u|^2 = |u_A|^2 = |u_B|^2$, $|v|^2 = |v_A|^2 = |v_B|^2$, $l = u_A v_B^* = u_B v_A^*$, and $uv^* = u_A^* v_A = u_B v_B^*$.

The computation of a , b , etc., can be performed following the lines given in the Appendix A of [22], where they were

computed for the initial state $|EG\rangle$ and only for $\Delta m=0$. In terms of $z=\Omega r/c$ and $x=r/ct$, being r the interatomic distance, we find

$$a = \frac{4iKz^3}{3x} \left[\ln \left(1 - \frac{z_{\max}}{z} \right) + i\pi \right],$$

$$a' = \frac{-4iKz^3}{3x} \ln \left(1 + \frac{z_{\max}}{z} \right),$$

$$b = b'^* = \frac{\alpha d_i d_j}{\pi e^2} (-\nabla^2 \delta_{ij} + \nabla_i \nabla_j) I, \quad (11)$$

with $K=\alpha|\mathbf{d}|^2/(e^2 r^2)$ and $I=I_++I_-$, where

$$I_{\pm} = \frac{-ie^{-i(z/x)}}{2z} \left\{ \pm 2 \cos \left(\frac{z}{x} \right) e^{\pm iz} \text{Ei}(\mp iz) \right. \\ \left. + e^{-iz[1 \pm (1/x)]} \text{Ei} \left[iz \left(1 \pm \frac{1}{x} \right) \right] \right. \\ \left. - e^{iz[1 \pm (1/x)]} \text{Ei} \left[-iz \left(1 \pm \frac{1}{x} \right) \right] \right\} \quad (12)$$

for $x > 1$, having the additional term $-2\pi i e^{iz(1-1/x)}$ otherwise. $|u|^2$, $|v|^2$, I , $u_B u_A^*$, $v_A v_B^*$, and uv^* have been computed in [22]. Besides

$$g = u_B u_A' + u_A u_B', \quad g' = v_A v_B' + v_B v_A',$$

$$f = \theta(t_1 - t_2) [v_A(t_1) u_A'(t_2) + u_A(t_1) v_A'(t_2) + v_B(t_1) u_B'(t_2) \\ + u_B(t_1) v_B'(t_2)],$$

$$f' = \theta(t_1 - t_2) [u_A(t_1) v_A'(t_2) + u_A'(t_1) v_A(t_2) + u_B(t_1) v_B'(t_2) \\ + u_B'(t_1) v_B(t_2)], \quad (13)$$

where the primes are introduced to discriminate between the two single photons.

We will use the concurrence $C(\rho)$ [26] to compute the entanglement, which for a state like (9) is given by, if $\sqrt{\rho_{22}\rho_{33}} + |\rho_{23}| > \sqrt{\rho_{11}\rho_{44}} + |\rho_{14}|$,

$$C(\rho_{AB}) = \max \left(\frac{2(|\rho_{23}| - \sqrt{\rho_{11}\rho_{44}})}{N}, 0 \right) \quad (14)$$

and

$$C(\rho_{AB}) = \max \left(\frac{2(|\rho_{14}| - \sqrt{\rho_{22}\rho_{33}})}{N}, 0 \right) \quad (15)$$

otherwise.

If we take $\alpha=\sqrt{p}$ and $\beta=\sqrt{1-p}$, we find that ESD appears at a range of values of p that decreases with increasing r , in agreement with [7]. Although this would suggest that ESD disappear for r large enough, we find that there are high values of p for which ESD exists for arbitrary large r . In Fig. 1, we represent $C(\rho_{AB})$ in front of x for different values of z and $p=0.98$. ESD occurs at $z/x=\Omega t$ of the order of 10^7 . Thus, as z (that is r) grows, ESD is shifted to higher values of x . It is also interesting to analyze the phenomenon of

FIG. 1. Concurrence $C(\rho_{AB})$ in front of $x=r/ct$ for $p=0.98$ and $z=\Omega r/c=2 \times 10^6$ (solid line), 5×10^6 (dashed line) and 2×10^7 (dotted line). In the latter case sudden death and revival of entanglement occur for $x > 1$.

entanglement revival, discovered in these systems in [7]. We find that the dark periods [7] between death and revival have larger time durations for increasing z . Besides, although in [7] the revival is described as a consequence of the photon exchange, for r sufficiently large both the ESD and the revival can occur for $x > 1$, where photon exchange is not allowed. We think that the explanation for entanglement revival is closer to the spirit of [5,11] where entanglement revival between noninteracting atoms is interpreted as coming from entanglement transfer between different parts of the system. We shall discuss this point in the following sections.

In Fig. 2 we sketch the dependence with p . Although sudden death and revivals appear in a very restricted range of the parameter, they are only a particular case of the generic behavior of entanglement observed in a wider range, which can be described as disentanglement up to a minimum value and growth of quantum correlations since then.

IV. ATOM-FIELD ENTANGLEMENT

Tracing (4) over states of atom A (B) the reduced atom-field density matrix ρ_{BF} (ρ_{AF}) is obtained. Taking the basis $\{|E0\rangle, |E1\rangle, |E2\rangle, |G0\rangle, |G1\rangle, |G2\rangle\}$, we have

FIG. 2. Concurrence $C(\rho_{AB})$ in front of $x=r/ct$ for $z=\Omega r/c=2 \times 10^7$ and $p=0.97$ (solid line), $p=0.98$ (dashed line) and $p=0.99$ (dotted line). In the first case, entanglement decreases as t grows up to a minimum value and begin to grow since then. This behavior becomes entanglement sudden death and revival when the minimum value is 0 for higher values of p . $C(\rho_{AB})$ tends to 0 as $x \rightarrow \infty$ and $p \rightarrow 1$.

$$\rho_{BF} = \rho_{AF} = \frac{1}{N'} \begin{pmatrix} \rho'_{11} & 0 & \rho'_{13} & 0 & \rho'_{15} & 0 \\ 0 & \rho'_{22} & 0 & \rho'_{24} & 0 & \rho'_{26} \\ \rho'^*_{13} & 0 & \rho'_{33} & 0 & \rho'_{35} & 0 \\ 0 & \rho'^*_{24} & 0 & \rho'_{44} & 0 & \rho'_{46} \\ \rho'^*_{15} & 0 & \rho'^*_{35} & 0 & \rho'_{55} & 0 \\ 0 & \rho'^*_{26} & 0 & \rho'^*_{46} & 0 & \rho'_{66} \end{pmatrix} \quad (16)$$

with

$$\begin{aligned} \rho'_{11} &= |\alpha(1+a) + \beta b'|^2, & \rho'_{22} &= \rho'_{55} = \rho_{22}, \\ \rho'_{33} &= |\alpha f + \beta g'|^2, & \rho'_{44} &= |\alpha b + \beta(1+a')|^2, \\ \rho'_{66} &= |\alpha g + \beta f'|^2, & \rho'_{13} &= [\alpha(1+a) + \beta b'](\alpha f + \beta g'), \\ \rho'_{15} &= [\alpha(1+a) + \beta b'](\alpha u_B + \beta v_A)^*, \\ \rho'_{24} &= (\alpha u_A + \beta v_B)[\beta(1+a') + \alpha b]^*, \\ \rho'_{26} &= (\alpha u_A + \beta v_B)(\alpha g + \beta f')^*, \\ \rho'_{35} &= (\alpha f + \beta g')(\alpha u_B + \beta v_A)^*, \\ \rho'_{46} &= [\alpha b + \beta(1+a')](\alpha g + \beta f')^*, \\ N' &= \rho'_{11} + \rho'_{22} + \rho'_{33} + \rho'_{44} + \rho'_{55} + \rho'_{66}. \end{aligned} \quad (17)$$

There are no operational generalizations of concurrence for mixed states in 2×3 dimensions like the ones in Eq. (16). We will use the negativity [27] $N(\rho)$, which is the absolute value of the sum of the negative eigenvalues of the partial transposes of a state ρ . For the 2×2 and 2×3 cases $N(\rho) > 0$ is a necessary and sufficient condition for ρ to be entangled.

Up to second order in perturbation theory, we have that $N' = N$ and that the nonzero eigenvalues of the partial transposes of both ρ_{BF} and ρ_{AF} are

$$\lambda_{\pm} = \frac{\rho'_{11} + \rho'_{55} \pm \sqrt{(\rho'_{11} - \rho'_{55})^2 + 4|\rho'_{24}|^2}}{2N'} \quad (18)$$

and

$$\lambda'_{\pm} = \frac{\rho'_{44} + \rho'_{55} \pm \sqrt{(\rho'_{44} - \rho'_{22})^2 + 4|\rho'_{15}|^2}}{2N'} \quad (19)$$

being zero the other two. In Eqs. (18) and (19) only the terms up to second order are retained. Therefore, if $|\rho'_{24}|^2 > \rho'_{11}\rho'_{55}$ then $\lambda_- < 0$ and if $|\rho'_{15}|^2 > \rho'_{22}\rho'_{44}$ then $\lambda'_- < 0$.

In Fig. 3 we represent $N(\rho_{BF}) = N(\rho_{AF})$ in front of x for same values of p and z of Fig. 1. We see that the negativity grows from 0 at $x \rightarrow \infty$ ($t=0$) to its maximum value and then starts to decrease and eventually vanishes, following the opposite cycle to the entanglement of ρ_{AB} .

Although it would be interesting to look for conservation rules of entanglement like the ones in [5, 11, 12], this search is beyond the focus of this paper since in our study we are

FIG. 3. Negativity $N(\rho_{BF}) = N(\rho_{AF})$ in front of $x = r/ct$ for $p = 0.98$ and $z = \Omega r/c = 2 \times 10^6$ (solid line), 5×10^6 (dashed line), and 2×10^7 (dotted line). Entanglement increases from 0 at $x \rightarrow \infty$ up to a maximum value and then decreases and vanishes eventually.

using different entanglement measures in Hilbert spaces of different dimensions. Besides, except for the concurrence between atoms A and B , the rest of the concurrences in the mentioned papers do not have obvious counterparts in our case. But it is clear that in general the entanglement cycle between atoms is correlated with the entanglement cycle between each atom and the field, as can be seen in Fig. 4 in a particular case. Although atom-field entanglement may change while the other remains zero, both entanglements cannot increase or decrease at the same time.

V. TRIPARTITE ENTANGLEMENT

Tripartite entanglement has been widely studied in terms of the entanglement of the different bipartitions $A-BC$, $B-AC$, $C-AB$ in the system [28–30], where A , B , and C stand for the three parties. Here, we will compute the I concurrences [31] C_{A-BF} , C_{B-AF} , C_{F-AB} , where $C_{J-KL} = \sqrt{2(1 - \text{Tr } \rho_J^2)}$, where J runs from A to F and KL from BF to AB , respectively, being ρ_J the reduced density matrix of J . A and B stand for the atoms, and F for the field.

Tracing (4) over BF (AF), we find the following density matrices ρ_A (ρ_B):

FIG. 4. Negativity $N(\rho_{BF}) = N(\rho_{AF})$ (solid line) and concurrence $C(\rho_{AB})$ (dashed line) in front of $x = r/ct$ for $p = 0.98$ and $z = \Omega r/c = 5 \times 10^6$. Entanglement atom-atom cycle is clearly correlated with the atom-field cycle, although the sum is not a conserved quantity. Although atom-field entanglement may change while the other remains zero, both entanglements cannot increase or decrease at the same time.

FIG. 5. I concurrence $C_{A-BF}=C_{B-AF}$ in front of $x=r/ct$ for $p=0.98$ and $z=\Omega r/c=2 \times 10^5$ (solid line), 5×10^5 (dashed line), and 1×10^6 (dotted line). Entanglement disappears faster than the entanglement between the atoms (Fig. 1) and remains 0 since then.

$$\rho_A = \rho_B = \frac{1}{N_A} \begin{pmatrix} \rho_{A11} & 0 \\ 0 & \rho_{A22} \end{pmatrix}, \quad (20)$$

where $\rho_{A11}=\rho'_{11}+\rho'_{33}+\rho_{22}$ and $\rho_{A22}=\rho'_{44}+\rho'_{66}+\rho_{22}$ and $N_A=\rho_{A11}+\rho_{A22}$. In Fig. 5 we sketch the behavior of C_{A-BF} and C_{B-AF} in front of x for different values of z . Entanglement vanishes before the death of the entanglement between A and B , and does not have a revival. Besides, ESD appears in a wider range of p , as can be seen in Fig. 6.

Now, tracing (4) over AB we obtain the reduced density matrix of the field ρ_F ,

$$\rho_F = \frac{1}{N_F} \begin{pmatrix} \rho_{F11} & 0 & \rho_{F13} \\ 0 & \rho_{F22} & 0 \\ \rho_{F13}^* & 0 & \rho_{F33} \end{pmatrix}, \quad (21)$$

where $\rho_{F11}=\rho'_{11}+\rho'_{44}$, $\rho_{F22}=2\rho_{22}$, $\rho_{F33}=\rho'_{33}+\rho'_{66}$, $\rho_{F02}=\rho'_{13}+\rho'_{46}$, and $N_F=\rho_{F11}+\rho_{F22}+\rho_{F33}$. In Fig. 7 we represent C_{F-AB} in front of x for the same values of z and p as in Fig. 5. Entanglement grows from 0 to a maximum value at $x \approx 0.1$ and then decreases. The growth of C_{F-AB} is correlated with the decrease of C_{A-BF} and C_{B-AF} in the same way as the magnitudes analyzed in the preceding section, as can be seen in Fig. 8 for a particular case.

FIG. 6. I concurrence $C_{A-BF}=C_{B-AF}$ in front of $x=r/ct$ for $z=\Omega r/c=2 \times 10^6$ and $p=0.50$ (solid line), $p=0.75$ (dashed line), and $p=0.98$ (dotted line). Entanglement sudden death occurs for a wider range than the entanglement between the atoms (Fig. 2).

FIG. 7. I concurrence C_{F-AB} in front of $x=r/ct$ for $p=0.98$ and $z=\Omega r/c=2 \times 10^5$ (solid line), 5×10^5 (dashed line), and 1×10^6 (dotted line). Entanglement grows from 0 to its maximum value at $x \approx 0.1$ and then decreases.

VI. CONCLUSIONS

We have analyzed in a previously unexplored space-time region the entanglement dynamics of a system consisting in a pair of neutral two-level atoms A and B interacting with a common electromagnetic field F . At $t=0$ atoms are in the Bell state $\sqrt{p}|EE\rangle + \sqrt{1-p}|GG\rangle$ and the field in the vacuum state. The evolution of this state has been considered within the non-Markovian, non-RWA approach of quantum electrodynamics up to second order in perturbation theory. We find ESD and revival of entanglement in the reduced state of the atoms, in a range of p that decreases with the interatomic distance r , in agreement with the results obtained with master equations [7]. For r large enough, we find that the revival of entanglement can occur with $r > ct$ and therefore is not a consequence of photon exchange between the atoms. We find that this phenomenon is strongly related to the transfer of entanglement between the different subsystems of two parties that coexist in the entire system: We obtain a type of entanglement cycle for the atom-field reduced states opposite to the atom-atom one. We have considered also the different bipartitions of the system, namely $A-BF$, $B-AF$, and $F-AB$, finding similar relationships between their entanglement cycles.

ACKNOWLEDGMENTS

This work was supported by Spanish MEC FIS2005-05304 and CSIC 2004 5 OE 271 projects.

FIG. 8. I concurrence C_{F-AB} (solid line) and $C_{A-BF}=C_{B-AF}$ (dashed line) in front of $x=r/ct$ for $z=\Omega r/c=2 \times 10^5$ and $p=0.98$. Both magnitudes cannot increase or decrease at the same time.
