EFFECTS OF MILK CASEIN HYDROLYZATE SUPPLEMENTED WITH
PHYTOSTEROLS ON HYPERTENSION AND LIPID PROFILE IN
HYPERCHOLESTEROLEMIC HYPERTENSIVE RATS

1. Introduction

Hypertension and hypercholesterolemia are two major controllable risk factors of cardiovascular diseases (CVD), and have become the leading cause of morbidity and mortality worldwide, representing a continuous challenge to public health efforts (O'Donnell & Elosua, (2008). It has been established that high blood pressure combined with cholesterol levels over the desirable limits cause oxidative stress, impairment of endothelial function, vascular inflammatory responses and atherosclerosis (Ghiadoni, Taddei, & Virdis, 2012; Koh, Oh, & Quon, 2009). Besides pharmacological therapy, lifestyle and nutritional factors play a significant role in the prevention and treatment of pathologies as hypertension and hypercholesterolemia. The food industry, in association with research and public health institutions, has focused on the development of novel functional ingredients that aid in maintaining a normal blood pressure. These products could avoid the requirement to take antihypertensive drugs in borderline subjects (Hartmann & Meisel, 2007; Hernandez-Ledesma, Contreras, & Recio, 2011).

Epidemiological studies suggest that the dietary intake of milk and dairy foods is related to a decreased risk of hypertension (Engberink et al., 2009). Besides their high mineral content (e.g., calcium, potassium and magnesium) that can lower blood pressure (van Mierlo et al., 2006), other milk components, such as proteins and their hydrolyzed products, have been also linked to the antihypertensive effect of dairy products (Svetkey et al., 1999; Toledo et al., 2009; Van Meijl & Mensink, 2011). In the last two decades, antihypertensive effects of some peptides generated from milk proteins have been evaluated in experimental animals (Ehlers et al., 2011; Jäkälä et al., 2009a; Jauhiainen et al., 2010; Martínez-Maqueda et al., 2012; Sánchez-Rivera et al., 2016; Tavares et al., 2012). In this regard, several clinical trials have investigated the impact of lactotripeptides (isoleucine-proline-proline and valine-proline-proline) on blood pressure and vascular function, but only a few have examined the effects of other peptides from casein

hydrolyzates (Fekete, Givens, & Lovegrove, 2013; Pripp, 2008). Most of these peptides have demonstrated ACE-inhibitory activity, which is considered as one of the best strategies for hypertension management, nevertheless other mechanisms of action as antioxidant activity and opioid receptor agonist effect cannot be discarded (Nongonierma & FitzGerald, 2015).

A hydrolyzate obtained by the action of pepsin on casein, containing the α_{s1} -casein-derived peptides RYLGY and AYFYPEL, has been patented and commercialized under the name of Lowpept[®] due to its antihypertensive properties demonstrated in both, spontaneously hypertensive rats (SHR) (Contreras et al, 2009 and 2011; Sánchez et al., 2011) and hypertensive patients (Recio et al., 2011).

On the other hand, several food compounds such as long chain omega-fatty acids and phytosterols can exert beneficial cardiovascular effects by lowering plasma total cholesterol (TC) and low density lipoprotein-cholesterol (LDLc) (Lees et al., 1977; Lopez-Huertas, 2010; Marangoni & Andrea, 2010; Neil, Meijer, & Roe, 2001; Ras et al., 2016). The inhibition of cholesterol absorption in intestine is the main mechanism of action of phytosterols arising from chemical structure similarities between phytosterols and cholesterol (Calpe-Berdiel, Escolà-Gil, & Blanco-Vaca, 2009). The effects of phytosterols and phytosterol esters on vascular function and blood pressure are controversial and useful effects beyond lowering cholesterol have been suggested.

Hypertension and high cholesterol levels are two risk factors present in a large part of the population susceptible of suffering coronary heart disease or stroke (Makovac, Thayer, & Ottaviani, 2016; Okopień, Bułdak, & Bołdys, 2016).

Although the beneficial effects of the administration of phytosterols or milk peptides in cardiovascular health have been reported in different studies, few have investigated the co-administration (Ehlers et al., 2012; Turpeinen et al., 2009). Therefore, the aim of this study was to investigate if the addition of phytosterols to a casein hydrolyzate could have

beneficial synergistic effects on the management of hypertension and dyslipidemia. We assessed the effect of chronic treatment on blood pressure, vascular function, lipid profile and oxidative stress in hypercholesterolemic hypertensive rat.

2. Materials and methods

2.1. Experimental protocol

All the experiments were performed according to the European Union guidelines for the ethical care and use of laboratory animals and the protocol was approved by the Bioethics Committee of University of Salamanca (Register N°: 006N°201400023665). Twenty-four male SHR 13-week old (Janvier Labs, Le Genest Saint Isle, France) were housed in boxes of 3-4 rats and maintained at a temperature of 23 °C with 12 h light/dark cycles. Rats were fed on a solid standard diet (Global Diet 2014, Harlan Laboratories, Inc., Indianapolis, IN, USA) with *ad libitum* intake.

After 14 days of adaptation, baseline blood pressure measurements were performed. The systolic blood pressure (SBP) was measured in awake rats using the CODA tail-cuff blood pressure system (Kent Scientific, Torrington, CT, USA). This system utilizes volume pressure recording sensor technology to measure the rat tail blood pressure. Before the measurements, the rats were kept at 30-35 °C for 10-15 min to make detectable the pulsations of the tail artery. Arterial blood pressure measurements were carried out the same time of day (between 9 a.m. and 13 p.m.) in order to avoid the influence of the circadian cycle, and the values of SBP were obtained by estimating the average reading of 8-10 measurements. Thereafter, based on the SBP values and body weights, animals were randomized into four groups (n=6).

Group C: control SHR fed a standard diet.

Group CH: hypercholesterolemic SHR, rats fed a high-cholesterol diet (standard diet supplemented with 1% cholesterol and 0.25% cholic acid).

Group CHL: hypercholesterolemic SHR treated with milk casein hydrolyzate (300 mg/kg/day) incorporated in the chow.

Group CHLP: hypercholesterolemic SHR treated with milk casein hydrolyzate (300 mg/kg/day) and phytosterols (450 mg/kg/day) incorporated in the chow.

The body weight (BW) was recorded weekly and blood pressure monitored every two weeks in all groups during the experimental period. Feed consumption was controlled every two days.

At the end of the treatment (8 weeks), animals were anaesthetized with sodium pentobarbital (60 mg/kg BW, i.p.) and blood samples were collected. After that, tissues (heart, liver and aorta) were immediately harvested, placed in chilled Krebs solution (composition in mM: NaCl, 118; KCl, 4.7; CaCl₂, 2.5; KH₂PO₄, 1.2; MgSO₄, 1.2; NaHCO₃, 25 and glucose, 11, pH= 7.4) and appropriately processed for further studies.

Blood samples were centrifuged at 350 g for 10 min, at 4 °C, to obtain the plasma that was kept at -80 °C until use.

2.2. Left ventricular hypertrophy

The atrium was removed from the heart and all the epicardial fat was scraped off. The right and the left ventricles were separated, regarding the interventricular septum as an integral part of the left ventricle, and this portion was weighed. The left ventricular hypertrophy (LVH) index was calculated using left ventricle weight/BW ratio.

2.3. Morpho-histology of liver

Isolated liver was washed with chilly Krebs solution and moisture was eliminated with filter paper. The liver hypertrophy (LH) index was determined using liver weight/BW ratio.

A portion of large lobe of the liver was fixed in 10% formaldehyde for 72 hours. Fixed specimens were processed for paraffin embedding and 5 µm slices were stained with

hematoxylin-eosin. Histological sections were examined under an optical microscope and images were captured using a high-resolution digital camera (Olympus DP50, Tokyo, Japan). Size of hepatocytes was measured as an average of 10 hepatocytes taken from different zones of histological sections using ImageJ software (US National Institutes of Health, <http://rsb.info.nih.gov/ij/>). The hepatic steatosis was measured as percent area fraction of fat vacuole surrounding periportal area/total area of image. Adobe Photoshop (Adobe Photoshop® CS3, Microsoft) program was used to image analysis.

2.4. Biochemical parameters measurement

Triacylglycerols (TG), TC, high density lipoprotein-cholesterol (HDLc), alanine transaminase (ALT), aspartate transaminase (AST) levels were analyzed in plasma using reagent strips for quantitative measurement (Spotchem™ II, Arkay, Shiga, Japan) in a fully automatic biochemical analyzer (Spotchem™ EZ sp-4430, Arkay, Shiga, Japan). LDLc was calculated according to the formula: $LDLc = TC - (HDLc + TG/5)$ and the atherogenic index (AI) was calculated as follows: $AI = (TC - HDLc) / HDLc$ (Olmez et al., 2015).

2.5. Lipid peroxidation (TBARS)

Lipid peroxidation, a marker of oxidative stress, was estimated in plasma by measurement of thiobarbituric acid-reactive substances (TBARS) previously described by Ohkawa, Ohishi and Yagi (1979) with minor modifications (Kassan et al., 2009). The results were expressed as concentration of TBARS (μM).

2.6. Vascular reactivity measurements

The thoracic aorta was carefully cleaned of fat and connective tissue and cut into rings (3 mm length) that were placed between stainless steel hooks and set up in organ chambers

filled with 5 mL of Krebs solution, bubbled with carbogen (5% CO₂, 95% O₂) and kept at 37 °C. One of the hooks was fixed to the bath and the other connected to an isometric force transducer (UF1, Harvard apparatus Inc., Holliston, MA, USA). Force was recorded on a PC computer using Lab Chart version 3.4 software and a Power Lab/800 data acquisition system (AD Instruments, Oxford, UK). All rings were allowed to equilibrate for 1 h at a resting tension of 2 g. The Krebs solution was periodically changed and tension was reset during this period. Then, the vessels were exposed to phenylephrine (PE, 10⁻⁶ M) and the presence of functional endothelium was assessed by the ability of acetylcholine (ACh, 10⁻⁶ M) to induce relaxation. After a washout period, cumulative concentration-response curves to PE (10⁻⁸ to 10⁻⁴ M) were obtained. After pre-contraction with PE (10⁻⁶ M) and steady maximal contraction, cumulative concentration-response curves were obtained for ACh (10⁻⁸ to 10⁻⁴ M) or sodium nitroprusside (SNP, 10⁻⁹ to 10⁻⁴ M). Each curve was obtained in different rings.

Responses to PE were expressed as mg of contraction and responses to ACh and SNP as percentage of PE contraction.

2.7. Detection of vascular superoxide anion

Superoxide anion (O₂^{•-}) production was assessed by lucigenin-enhanced chemiluminescence assay. Briefly, segments of thoracic aorta were incubated in ROS phosphate buffer (composition in mM: KH₂PO₄, 50; EGTA, 1 and sucrose, 150, pH=7.4) supplemented with ammonium diethyldithiocarbamate (DDC, 10 mM), gassed with carbogen and maintained at 37°C for 15 min. Then, samples were transferred into tubes containing ROS phosphate buffer, DDC (10 mM), nicotinamide adenosine dinucleotide phosphate (NADPH, 10⁻⁴ M) and lucigenin (5 µM). Lucigenin chemiluminescence was recorded every 10 s for 5 min in a luminometer (LUMAT LB-9507, Berthold Technologies,

Bad Wildbad, Germany). Production of $O_2^{\bullet-}$ is expressed as relative luminescence units (RLU)/min/mg dry tissue.

2.8. Compounds

The milk casein hydrolyzate (Lowpept[®]) was prepared using commercial casein (Promilk 85, Arras Cedex, France) that was hydrolyzed with food grade pepsin (Biocatalysts, Cardiff, UK), according to our previous paper (Contreras et al., 2011) and provided by Innaves S.A. (Vigo, Spain).

Phytosterols were a concentrate of sterols containing mainly sterols from vegetable oils (Vitasterol[®] S-80 WDP (90%), provided by Vitae Caps S.A., Toledo, Spain).

Cholesterol (PubChem CID: 5997); cholic acid (PubChem CID: 221493); acetylcholine chloride (PubChem CID: 6060); phenylephrine hydrochloride (PubChem CID: 5284443); sodium nitroprusside (PubChem CID: 11953895); thiobarbituric acid (PubChem CID: 2723628), trichloroacetic acid (PubChem CID: 6421), ammonium diethyldithiocarbamate (PubChem CID: 88794), nicotinamide adenosine dinucleotide phosphate (PubChem CID: 5884) and lucigenin (PubChem CID: 65099) were purchased from Sigma-Aldrich (Madrid, Spain). All other chemicals were of analytical grade. Stock solutions of the drugs were prepared in ultrapure water, stored at -20 °C and appropriate dilutions were made on the day of the experiments.

2.9. Statistical analysis

Data are expressed as means $\pm$ standard error of the mean (SEM). The cumulative concentration–response curves by ACh, SNP and PE were fitted to a logistic equation and the negative logarithm of the concentration producing half maximal effect (pD_2) were calculated. Concentration-response curves comparison was performed according to the extra sum of squares F-test principle. The level of statistical significance was determined

by one-way analysis of variance (ANOVA) followed by Bonferroni's test for multiple comparisons and two-way ANOVA for blood pressure data. Significance was accepted at $P < 0.05$. Fitting and statistical analysis were performed using GraphPad Prism[®] software (version 5.0; GraphPad Software, Inc., San Diego, CA, USA).

3. Results

3.1. Blood pressure

Blood pressure values during the 8 weeks treatment are presented in Fig. 1. The induction of hypercholesterolemic status did not alter the SBP. The long-term treatment with milk casein hydrolyzate with or without phytosterols decreased the SBP of the hypertensive hypercholesterolemic rats from 4 weeks of treatment. During the treatment, there were no significant differences in SBP values between CHL and CHLP groups.

3.2. Left ventricular hypertrophy

There were no differences in the daily dietary intake or in the BW among groups (Table 1). Hypercholesterolemic diet did not modify the LVH index compared with control group, but both treatments resulting in a significant reduction of this parameter (Fig. 2).

3.3. Morpho-histology of liver

In contrast to the normal healthy appearance of the liver in the C group, the high-cholesterol diet for 8 weeks induced an increase of liver size (Fig. 3). Liver from rats fed only with hypercholesterolemic diet exhibited increase in size hepatocytes ($CH=896\pm65$ versus $C=430\pm17 \mu m^2$, $p<0.05$), massive fatty changes and severe steatosis, as it is shown in histological sections (Fig. 4). Treatment with milk casein hydrolyzate failed to reduce hypertrophy ($CHL=855\pm27 \mu m^2$) and steatosis, however phytosterols addition

reversed the hepatocytes to normal values (CHLP=569±74 μm^2) and the hepatic steatosis was remarkably lower, and the hepatic cells exhibited normal histology.

3.4. Biochemical parameters and lipid peroxidation assessment

Table 1 summarizes the parameters measured in plasma in order to evaluate the changes on lipid profile, transaminases and the extent of lipid peroxidation between the different groups. The hypercholesterolemic diet (group CH) dramatically increased the plasmatic levels of TC, LDLc and AI, a slight decrease of HDLc was also measured and no significant changes were observed in TG levels, which demonstrated the hyperlipidemic model was successfully established. Even though the oral administration of milk casein hydrolyzate during 8 weeks did not cause any effect in preventing alterations related to the hypercholesterolemic status, the addition of phytosterols resulted in a significantly recovery of TC, LDLc levels and AI.

The levels of enzymes AST and ALT were greater in CH group compared with the C group, indicating that lipid accumulation was harmful to the liver. Treatment with milk casein hydrolyzate produced a significant reduction in ALT, and a slight attenuation in AST not statistically significant compared to the hypercholesterolemic SHR group untreated. The addition of phytosterols to casein hydrolyzate produced a greater effect at the level of these hepatic enzymes, obtaining similar values to the control SHR group.

Moreover, rats receiving the hypercholesterolemic diet showed a remarkable increase of lipid peroxidation products in plasma. Although the treatment with milk casein hydrolyzate slightly attenuated lipid peroxidation levels, only the incorporation of phytosterols to the diet was able to get a significant effect respect to CH group.

3.5. Vascular reactivity

Endothelium-dependent relaxation induced by ACh showed no difference between C ($E_{max}=42.2\pm2.1\%$ and $pD_2=7.5\pm0.2$) and CH groups ($E_{max}=45.8\pm2.0\%$ and $pD_2=7.5\pm0.1$), but the groups treated with milk casein hydrolyzate regardless of the presence ($E_{max}=57.4\pm4.1\%$ and $pD_2=7.7\pm0.3$) or absence ($E_{max}=57.0\pm3.7\%$ and $pD_2=7.5\pm0.2$) of phytosterols showed significantly greater relaxation to ACh (Fig. 5a). SNP-induced endothelium-independent relaxation reached proximately 100% in all groups. The sensibility to this agent was higher in vessels of treated animals with milk casein hydrolyzate ($pD_2=7.8\pm0.1$) or milk casein hydrolyzate plus phytosterols ($pD_2=7.9\pm0.1$) than in CH group and not differences between C and CH groups were observed ($pD_2=7.4\pm0.1$ and $pD_2=7.6\pm0.1$, respectively) (Fig. 5b).

Phenylephrine-induced contractile responses in aortic rings from different groups are shown in Fig. 6. Rings from rats fed with hypercholesterolemic diet did not modify the response to phenylephrine (C group, $E_{max}=2104\pm105$ mg and CH group, $E_{max}=2343\pm206$ mg), and treatment with milk casein hydrolyzate achieved a significantly reduction of contractile response ($E_{max}=1495\pm142$ mg). Additional treatment with phytosterols did not modify this response ($E_{max}=1707\pm219$ mg).

3.6. *Vascular superoxide anion*

The $O_2^{\bullet-}$ production stimulated by NADPH in aortic rings is shown in Fig. 7. Hypercholesterolemic diet caused an increase of this free radical. The treated groups with casein hydrolyzate shown statistical significant reduction in generation of $O_2^{\bullet-}$. Interesting, these levels were lower in group receiving casein hydrolyzate with phytosterols.

4. Discussion

This investigation has been conducted in SHR with experimentally induced hypercholesterolemia. SHR is a phenotype-driven rat experimental model in which

hypertension is associated with cardiac hypertrophy, endothelial dysfunction and oxidative stress; and extensively used in research since resembles human hypertension (Lerman et al., 2005). The diet-induced hypercholesterolemia is used to promote alterations on lipid profile, redox balance and liver damage (Abreu et al., 2014; Deepa & Varalakshmi, 2003). Hypertension and hypercholesterolemia are two major risk factors of cardiovascular diseases and great efforts are being made to control them.

The long-term effects of a milk casein hydrolyzate containing active peptides or fortified with phytosterols were investigated on blood pressure, morphological and histological alterations of organs, vascular function, lipid profile and oxidative stress. Phytosterols were included in the study to find out a possible additional effect on the aforementioned variables.

Our previous studies showed that long-term treatment with milk casein hydrolyzate containing the α_{s1} -casein derived peptides, RYLGY and AYFYPEL, attenuated the development of hypertension, exerted a cardiovascular protective effect in SHR (Sánchez et al., 2011) and decreased blood pressure (about 12 mmHg) in hypertensive subjects (Recio et al., 2011). Recently, bioactive milk peptides have gained interest because of their notable antihypertensive, antioxidant, anti-inflammatory, and hypocholesterolemic effects (Hsieh et al., 2015). In the current study, the casein hydrolyzate decreased SBP in hypercholesterolemic SHR, but any additional reduction on blood pressure was observed after supplementation with phytosterols. Therefore, we assume that phytosterols do not contribute to the antihypertensive effect. In this sense, Kim et al. (2008) also reported no effects on blood pressure in conscious SHR fed with a diet fortified with phytosterol esters for 9 weeks and other studies in human pointed at the ineffectiveness of phytosterols or stanols to reduce blood pressure (Hallikainen et al., 2006; Tapola et al., 2004).

Hypertension is a major cause of cardiac hypertrophy, which frequently leads to heart failure (Gradman & Alfayoumi, 2006). In concordance with our results on blood pressure

above mentioned, additional alterations in LVH caused by hypercholesterolemic diet were not observed, however treatment with milk casein hydrolyzate regardless of the presence of phytosterols decreased the hypertrophic index.

It is known that SHR from 10 to 12 week-old, show marked endothelial dysfunction (Bernatova et al., 2009). As expected, our results on vascular reactivity in aortic rings showed impaired endothelial function in control SHR fed a standard diet while the induction of a hypercholesterolemic status did not aggravate vascular dysfunction.

Lorkowska et al. (2006) reported similar results, justified by a modest lipid accumulation in the vascular wall insufficient to induce alterations in vascular function.

We had previously reported that relaxation to ACh on aortic and mesenteric rings from SHR improved after 6-week treatment with the casein hydrolyzate and contraction to phenylephrine was lower (Sánchez et al. 2011). Here, using aorta from hypercholesterolemic SHR we corroborated the benefits of casein hydrolyzate on endothelial function and evidenced the ineffectiveness of supplementation with phytosterols.

In agreement with our results, other researchers also observed no additional effects on vasorelaxation response in arteries from SHR treated with fermented milk products containing tripeptides when plant sterols were co-administered (Ehlers et al., 2011 and 2012; Jäkälä et al., 2009b). It has to be noted that, both, milk casein hydrolyzate alone or combined with phytosterols increased the sensitivity of the aortic rings to the endothelium-independent vasodilator SNP. However, previous reports had not shown differences on response to SNP between control animals and treated with milk casein derived products (Jäkälä et al., 2009a and 2009b; Sánchez et al., 2011). It can be hypothesized that this discrepancy could be due to the use of older rats in the present study, in which arterial dysfunction might have further progressed, and thus, the positive effect of milk casein

hydrolysate on smooth muscle cells could be more pronounced; in addition to a longer treatment period in comparison with previous studies.

The effect of diets supplemented with phytosterols on vascular function have not received much attention, and it is difficult to precise its effect, because they are often incorporated into products together with other bioactive components. In this regard, Hallikainen et al. (2006) administered either plant sterols or stanols esters to hypercholesterolemic subjects for 10 weeks, and this treatment did not affect the dilatation of the brachial artery. In another study, plant sterols consumption for 2 years did not significantly improve carotid artery compliance in healthy subjects (Raitakari, Salo, & Ahotupa, 2008). A study with male C57/Bl6 mice fed with 2% plant sterol ester-supplemented diet for 4 weeks showed that the endothelium-dependent relaxation of aortic rings was slightly impaired in comparison to the controls (Weingartner et al., 2008).

Elevated plasmatic levels of TC and LDLc along with low HDLc are often associated with premature atherosclerosis and CVD (Assmann & Gotto, 2004). High cholesterol diet raises plasma LDLc levels and oxidative stress, both result in the production of oxidized LDLc and thereby increases atherosclerotic plaque formation. The cardioprotective effects of HDLc are associated to its role in reversing cholesterol transport, its effects on endothelial cells, and its antioxidant activity (Akalin-Çiftçi et al., 2015). As expected, our results in hypercholesterolemic untreated rats reproduced this pattern with lower HDLc and higher TC and LDLc levels than those from animals receiving standard diet, which led to an increased AI. Morphological and biochemical studies also revealed liver injury characterized by hepatomegaly and high levels of AST and ALT enzymes. Moreover, histology revealed large size hepatocytes and steatosis in CH group. Similar results have been reported by others researchers in Goto-Kakizaki and Wistar rats (Kengkoom et al., 2013) and Fischer rats (Abreu et al., 2014) after hypercholesterolemic diets. Treatment with casein hydrolyzate alone failed to revert most of the alterations previously indicated,

thus it seems that phytosterols were solely responsible for improving the lipidic profile and hepatic damage.

Both hypertension and hypercholesterolemia are associated with a large increase in reactive oxygen species, a situation which finally ends with oxidative stress that promotes cell growth, inflammation, extracellular matrix deposition, etc; resulting in endothelial dysfunction, cardiac hypertrophy, lipid peroxidation, etc. (Ellulu et al., 2016; Montezano & Touyz, 2014). To demonstrate any implication of the treatments on oxidative stress we measured the TBARS and $O_2\bullet^-$. In this sense, it is well known that these biomarkers are higher in SHR than in normotensive rats. We found that both were significantly increased when SHR were fed with the hypercholesterolemic diet. Unlike results previously discussed, the co-administration of phytosterols was effective, since the reduction of lipid peroxidation in the groups of animals treated with milk casein hydrolysate, respect to CH group, achieved statistical significance with the addition of phytosterols. The determination of $O_2\bullet^-$ supported the antioxidant action of the hydrolysate and the synergistic effect of phytosterols. It is worth noting that, in addition to the antihypertensive effect, in vitro scavenger activity has been already reported for peptides from this casein hydrolysate (Contreras et al., 2009) and otherwise, phytosterols have displayed an important hypolipidemic activity (Neil, Meijer, & Roe, 2001; Marangoni & Andrea, 2010). Therefore, the joint administration of both compounds would be suitable when hypertension and hypercholesterolemia coexist.

5. Conclusion

In hypercholesterolemic hypertensive rats, chronic treatment with milk casein hydrolysate improved the parameters related to the hypertensive process, while the incorporation of phytosterols prevented the alterations caused by the hipercholesterolemia. Just the increase in oxidative stress, present in hypertension and hipercholesterolemia, showed a

greater reduction after co-administration. Therefore, the administration of the casein hydrolyzate fortified with phytosterols would be indicated when both disorders occur together.

Conflict of interest

The authors declare no conflicts of interest.

FIGURES CAPTIONS

Figure 1. Systolic blood pressure (SBP) in control SHR (C), untreated hypercholesterolemic SHR (CH), treated hypercholesterolemic SHR with milk casein hydrolyzate (CHL) or milk casein hydrolyzate plus phytosterols (CHLP).

Values are expressed as mean $\pm$ SEM of 6 rats.

P<0.01, *P<0.001 vs. CH.

Figure 2. Left ventricular hypertrophy (LVH) index at the end of study (8 weeks) in control SHR (C), untreated hypercholesterolemic SHR (CH), treated hypercholesterolemic SHR with milk casein hydrolyzate (CHL) or milk casein hydrolyzate plus phytosterols (CHLP).

Values are expressed as mean $\pm$ SEM of 6 rats.

P<0.01, *P<0.001 vs. CH.

Figure 3. Liver hypertrophy (LH) index at the end of study (8 weeks) in control SHR (C), untreated hypercholesterolemic SHR (CH), treated hypercholesterolemic SHR with milk casein hydrolyzate (CHL) or milk casein hydrolyzate plus phytosterols (CHLP).

Values are expressed as mean $\pm$ SEM of 6 rats.

###P<0.001 vs. C; *P<0.05 vs. CH; +P<0.05 vs. CHL.

Figure 4. Histological sections of liver ($\times 20$) and hepatic steatosis area (%) at the end of study (8 weeks) in control SHR (C), untreated hypercholesterolemic SHR (CH), treated hypercholesterolemic SHR with milk casein hydrolyzate (CHL) or milk casein hydrolyzed plus phytosterols (CHLP).

Values are expressed as mean $\pm$ SEM of 6 rats.

###P<0.001 vs. C; *** P<0.001 vs. CH; +++ P<0.001 vs. CHL.

Figure 5. Cumulative concentration–response curves to acetylcholine (**a**) and sodium nitroprusside (**b**) in pre-constricted aortic rings from control SHR (C), untreated hypercholesterolemic SHR (CH), treated hypercholesterolemic SHR with milk casein hydrolyzate (CHL) or milk casein hydrolyzed plus phytosterols (CHLP).

Values are expressed as mean $\pm$ SEM of 6 rats.

P<0.01, *P<0.001 vs. CH.

Figure 6. Cumulative concentration–response curves to phenylephrine in aortic rings from control SHR (C), untreated hypercholesterolemic SHR (CH), treated hypercholesterolemic SHR with milk casein hydrolyzate (CHL) or milk casein hydrolyzed plus phytosterols (CHLP).

Values are expressed as mean $\pm$ SEM of 6 rats.

*P<0.05, **P<0.01 vs. CH.

Figure 7. Vascular superoxide anion ($O_2^{\bullet-}$) generation stimulated by NADPH addition in aortic rings from control SHR (C), untreated hypercholesterolemic SHR (CH), treated hypercholesterolemic SHR with milk casein hydrolyzate (CHL) or milk casein hydrolyzed plus phytosterols (CHLP).

Values are expressed as mean $\pm$ SEM of 6 rats.

###P<0.001 vs. C; * P<0.05, *** P<0.001 vs. CH.

Table 1.

Table 1. Daily intake of feed, water consumption, weight gain, lipid profile, atherogenic index (AI), transaminases (AST, ALT) and lipid peroxidation (TBARS) at the end of experiment (8 weeks) in control SHR (C), untreated hypercholesterolemic SHR (CH), treated hypercholesterolemic SHR with milk casein hydrolyzate (CHL) or milk casein hydrolyzate plus phytosterols (CHLP).

	C	CH	CHL	CHLP
Feed intake (g/day)	23.1 ± 0.2	22.8 ± 0.3	22.7 ± 0.2	23.3 ± 0.2
Water consumption (mL/day)	35.4 ± 1.2	36.2 ± 0.9	37.1 ± 1.1	36.7 ± 0.8
Weight gain (g/8 weeks)	93.8 ± 8.4	89.0 ± 4.6	102.8 ± 5.3	109.4 ± 4.3
TC (mg/dL)	84.5 ± 6.8	145.3 ± 7.6 ^{###}	147.7 ± 10.4	94.5 ± 7.0 ^{**,+++}
TG (mg/dL)	97.0 ± 19.3	118.7 ± 16.3	81.2 ± 9.6	98.7 ± 7.0
LDLc (mg/dL)	36.5 ± 5.2	93.8 ± 9.0 ^{###}	103.1 ± 9.8	42.6 ± 7.4 ^{**,+++}
HDLc (mg/dL)	38.0 ± 3.7	27.8 ± 1.2 [#]	28.3 ± 2.8	32.1 ± 1.5
AI	1.3 ± 0.3	4.3 ± 0.4 ^{###}	4.5 ± 0.7	2.0 ± 0.2 ^{**,++}
AST (IU/L)	42.2 ± 4.3	103.8 ± 15.6 ^{##}	86.2 ± 14.7	48.6 ± 2.5 [*]
ALT (IU/L)	24.8 ± 1.6	69.6 ± 4.0 ^{###}	31.4 ± 2.7 ^{***}	27.4 ± 3.8 ^{***}
TBARS (μM)	2.8 ± 0.1	4.3 ± 0.4 ^{###}	3.8 ± 0.2	3.2 ± 0.2 [*]

TC, total Cholesterol; TG, Triacylglycerols; LDLc, low density lipoprotein-cholesterol; HDLc, high density lipoprotein-cholesterol; AST, aspartate transaminase; ALT, alanine transaminase.

Values are expressed as mean ± SEM of 6 rats.

[#]P<0.05, ^{###}P<0.001 vs. C; ^{*}P<0.05, ^{**}P<0.01 vs. CH; ⁺⁺P<0.01, ⁺⁺⁺P<0.001 vs. CHL.
