ABSTRACT

ReO_3 were prepared by thermal treatment of the macromolecular $\text{Chitosan} \bullet (\text{ReCl}_3)_x$ and $\text{PSP-4-PVP} \bullet (\text{ReCl}_3)_x$ precursors. The plasmon band in the visible region for the as obtained ReO_3 from their visible spectra was observed at λ_{max} of 640 nm. The nature of the polymeric precursor is acting as a solid state template and influences the size and morphology of the metal oxides. For the first time, the photocatalytic degradation of methylene blue using ReO_3 was measured founding a moderated and high activity for ReO_3 arise from Chitosan and PSP-4-PVP precursors respectively. The inclusion of ReO_3 into SiO_2 was performed using a combined solution of the Chitosan and PVP precursors by the sol-gel method. Subsequent pyrolysis of the solid precursors $\text{Chitosan} \bullet (\text{ReCl}_3)_x(\text{SiO}_2)_y$ and $\text{PSP-4-PVP} \bullet (\text{ReCl}_3)_x(\text{SiO}_2)_y$ give rise to the nanocomposites $\text{ReO}_3/\text{SiO}_2$. The as obtained ReO_3 nanoparticles inside SiO_2 are small as 1 nm. The ReO_3 nanoparticles are distributed uniformly inside the matrix of SiO_2 , leading to stable semi porous materials suitable for high temperature catalytic application. The composites $\text{ReO}_3/\text{SiO}_2$ exhibit a moderate photocatalytic activity toward the degradation of methylene blue and similar to that of ReO_3 .

1 Introduction

Rhenium differ considerably from manganese, despite similarities in the stoichiometry of a few compounds (e.g. the series MnO_4^- , TcO_4^- , ReO_4^-). Re has little cationic chemistry but they have extensive chemistry in the IV, V and VI state [1]. Among rhenium oxides, ReO_3 exhibit some catalytic activity in organic reactions. Their activity is hugely enhanced at the nano-level [2,3]. The most interesting property of ReO_3 is their metallic behavior with conductivity closes that of copper [4-6].

Although isolated solution preparation methods for ReO_3 [4-9] is well documented, no solid-state general ways to prepare these nanostructured metal oxides have been reported. Re, metal oxides have been obtained by solvothermal treatment of the precursors $\text{Re}_2\text{O}_7 \bullet \text{C}_4\text{H}_8\text{O}_2$ at 200 °C [5]. ReO_3 nanowires have been prepared via a simple vapor transport at 300 °C [7] and their SERS activity toward aza-aromatic compounds has been measured [6]. The Photodegradation activity of methyl orange using ReO_3 has been measured found a high catalytic efficiency.

Here we report a general and suitable method for the preparation of Re metal oxides nanostructured materials [10-12]. Regarding to the possible application of these Re metal oxides, the first step is usually their incorporation in solid matrices. Additionally, when the application of these nanostructured metal oxides involves high temperatures, the metal oxide inside the matrix must be stable [13, 14]. The incorporation of metal-oxide nanoparticles into solid devices is not straightforward [13, 14] when they are produced via a solution phase method because the solid-state isolation of the nanoparticles usually causes nanoparticle agglomeration [15-18]. Thus, the incorporation of metal-oxide a nanoparticle generated directly from a solid-state approach appears to be the most reliable method.

A general method to prepare Re nanostructured metal oxides is shown in scheme 1. Stable nanocomposites// SiO_2 are obtained by a high temperature thermal treatment of the precursors Chitosan•(ReCl_3)_n// SiO_2 and PS-co-4-PVP•(ReCl_3)_n// SiO_2 , as seen in scheme 2.

Pyrolysis: The complexes of polymer-metal were placed into a box furnace (lab tech) using a temperature program of pyrolysis at 180 °C.

Preparation of complexes of polymer-metal//Silica: In 20 ml dichloromethane, a stoichiometric amount of the polymer (1:1 polymer: complex) and 0,40 g of metal complexes was added. The heterogeneous mixture was stirred a room temperature for 8 days and then silica sols were added. This was prepared by mixing TEOS, acetic acid and H₂O mili-Q (1:4:4 TEOS: Acetic Acid: H₂O) at room temperature under stirring for 5 hours. The resulting gel was dried in a vacuum-oven at 80 °C and then calcined at 800 °C, except for Re which was calcined at 180 °C. The summary of the as obtained products is given in table 1.

Table 1: Yields, color and composition of the pyrolytic products from the respective precursors.

Precursor Polymer	Formula	Yield (%)	Color	Composition
(1)	PS-co-4-PVP●(ReCl ₃) _n	47	black	ReCl ₃ /ReO ₃
(2)	Chitosan●(ReCl ₃)	56	black	ReCl ₃ /ReO ₃
(3)	PS-co-4-PVP●(ReCl ₃) _n //SiO ₂	99	grey	ReO ₃ /SiO ₂
(4)	Chitosan●(ReCl ₃) _n //SiO ₂	64	grey	ReO ₃ /SiO ₂

Characterization: X-ray diffraction (XRD) was conducted at room temperature on a Siemens D-5000 diffractometer with θ -2 θ geometry. XRD data was collected using Cu- $K\alpha$ radiation (40 kV, 30 mA). Elemental microanalysis was performed by energy dispersive X-ray analysis using a NORAN Instrument micro-probe attached to the scanning electron microscopy. SEM images were acquired with a Philips EM 300 scanning electron microscope. Energy dispersive X-ray analysis (EDAX) was performed on a NORAN Instrument micro-probe attached to a JEOL 5410 scanning electron microscope. High-Resolution Transmission Electron Microscopy (HR-TEM) was performed using a JEOL 2000FX TEM microscope at 200 kV to characterize the average particle size, distribution and elemental and crystal composition. The average particle size was calculated using the Digital Micrograph software. Methylene Blue (MB) was used as a model compound to test the photocatalytic properties at

655 nm under UV-Vis illumination using a xenon lamp (150W) positioned 20 cm away from the photoreactor in a range 330-680 nm at room temperature, to avoid the self-degradation and thermal catalytic effects of cationic dye MB.

3. Results and Discussion

The Chitosan•(ReCl₃)_x and PSP-4-PVP•(ReCl₃)_x precursors were characterized by TG/DTA analysis. The presence and the degree coordination of the ReCl₃ to both polymer backbone were performed by TG analysis under air. The pyrolytic residue corresponds to ReO₃ in both cases and by mass difference and comparing with the macromolecular complex with a 100 % coordination the degree coordination can be estimated. Values are similar near at 80%. Thus the TG analysis confirm the presence of both Chitosan and PS-co-4-PVP slightly modified by coordination of the ReCl₃, see Electronic Supplementary Materials S2.

For the Chitosan•(ReCl₃)_x for instance the weight loss at 1883 °C can be assigned to the decomposition (carbonization) of the NH₂, CH₂OH and OH groups side to the main carbon ring of the Chitosan. On the other hand the weight loss at 360 °C can be assigned to the decomposition of the skeleton carbon of the Chitosan both weight loss modified to lesser temperatures than free Chitosan due to the coordination to the polymer decrease the thermal stability as is usually observed. These two main weight loss are accompanied of exothermal processes as observed by the respective exothermal peaks in the ATG curve at temperatures 221°C and around 540 °C.

XRD patterns of the as prepared ReO₃ from precursor both with Chitosan as solid state template are shown in figure 1. For the PSP-4-PVP precursor similar XRD pattern was found (not showed) For both templates, ReO₃ phase was obtained, in concordance with different preparation methods [5-8]. However some impurities of ReCl₃, in addition to rhenium oxide [4-6] were observed, see figure 1.

Fig. 1 XRD pattern of SEM image of ReO_3 from the precursor $\text{Chitosan} \bullet (\text{ReCl}_3)_x$.

SEM analysis for the pyrolytic product from $\text{PSP-4-PVP} \bullet (\text{ReCl}_3)_x$ shows a cuboid with a distorted ReO_3 [19] in figure 2.

Fig. 2 SEM image of ReO_3 a) and b).

HR-TEM for the ReO_3 sample obtained from the Chitosan precursor (see figures 4g and 4h) also shows typical particle sizes in the range of 10-20 nm. Similar well defined HRTEM images have been reported for ReO_3 obtained using a reduction method from the Re_2O_7 precursor [19].

Fig. 3 HRTEM of ReO_3 obtained from Chitosan (a) and (b).

Due to the well-known conductor behavior [5] nanostructured ReO_3 exhibits a plasmon band in the visible region [5]. For ReO_3 from their visible spectra (see electronic supplementary S3) a λ_{max} of 640 nm was observed shifted to most large wavelengths due to a sum most bigger size respect to those reported by Rao [5].

If the preparation methods (all in solution) for ReO_3 oxides are scarce [4-9], more limited are those for the oxides into SiO_2 , being the only one the core/shell $\text{ReO}_3/\text{SiO}_2$ structures reported by Ghosh et al. [8]. In this work we propose the incorporation of ReO_3 into sol-gel SiO_2 by using the respective macromolecular precursors $\text{Chitosan} \bullet (\text{ReCl}_3)_x$ and $\text{PSP-4-PVP} \bullet (\text{ReCl}_3)_x$. The phase purity of the $\text{ReO}_3//\text{SiO}_2$ products was characterized by X-ray diffraction.

Fig. 4 XRD of $\text{ReO}_3//\text{SiO}_2$ from $\text{Chitosan} \bullet (\text{ReCl}_3)_x // \text{SiO}_2$.

Finally, XRDs for $\text{ReO}_3//\text{SiO}_2$ nanocomposites produced from chitosan is shown in figure 4. The broad peak around $2\theta = 15^\circ\text{-}25^\circ$ observed in all these nanocomposites is typical of amorphous SiO_2 as matrix in metal oxide nanostructured inside [10-22]. Unfortunately, the diffraction peaks of ReO_3 are not clearly observed probably due to their small size, as it will be later confirmed by HR-TEM. The XRD for $\text{ReO}_3//\text{SiO}_2$ from the polymer PVP exhibits a similar XRD corroborating also the similar phase for $\text{ReO}_3//\text{SiO}_2$ (not showed).

From the HR-TEM image of the nanocomposite $\text{ReO}_3//\text{SiO}_2$ using the PVP precursor, small nanoparticles (~ 1 nm) of ReO_3 included in SiO_2 matrix can be observed, as shown in figure 5 (a)-(d). This can be due to the small confinement of the ReO_3 nanoparticles imposed by the SiO_2 network. It is also worth noting that the Chitosan precursor helps to enhance the distribution of ReO_3 particles along the SiO_2 matrix, as it was more difficult to find the nanoparticles on the sample obtained from the PVP precursor.

Fig. 5 HRTEM images of $\text{ReO}_3/\text{SiO}_2$ obtained from the PVP (a)-(b) and chitosan precursors (c)-(d).

Additional information about the uniform distribution of the ReO_3 nanoparticles inside silica was obtained by EDX mapping from SEM images, as shown in figure 6 for $\text{ReO}_3/\text{SiO}_2$ obtained for both precursors.

Fig. 6 EDX-elemental mapping of ReO_3 nanoparticles inside silica from precursor $(\text{Chitosan} \bullet (\text{ReCl}_3)_x // \text{SiO}_2)$ (a) and from precursor $\text{PSP-4-PVP} \bullet (\text{ReCl}_3)_x // \text{SiO}_2$ (b).

3.1 Photocatalytic behavior ReO_3

Methylene blue is one of the organic dyes which are extensively used in coloring paper, temporary hair colorant, dyeing cotton and coating for paper stock [23]. We use this dye as model dye to assay the photocatalytic properties of ReO_3 . The removal of this hazardous dye is considered as one of the growing needs in recent years. The photocatalytic experiments were carried on the catalyst ReO_3 samples with definite concentrations under dark conditions and with UV irradiations in attempts to prove their efficiency. Methylene blue (MB) was used a model dye to test the photocatalytic behavior of the nanostructured ReO_3 . In Electronic Supplementary Materials S4 are showed the absorption spectra vs time of the different oxides.

In addition, ReO_3 was also found to catalyze the photodegradation of MB with an efficiency of 53 % and 64% in 300 min, for the chitosan and PVP precursors, respectively. ReO_3 is an unusual transition metal oxide, as it presents a metallic behavior with conductivity close to that of copper [5]. Thus nanoparticles of rhenium trioxide produce SERS (surface-enhanced Raman spectra) effect for some organic compounds as pyridine [6]. In spite of this, their catalytic activity has been only proved in catalytic degradation of methyl orange [9]. Figure 7 (a) shows the plot of C/C_0 vs irradiation time for ReO_3 obtained from Chitosan as well as from PVP precursors, being the degradation capacity very similar for both samples. As shown in figure 7 (b), the kinetic of the degradation follow a first order processes for ReO_3 obtained both from Chitosan as well as from PVP precursors.

Fig. 7 (a) Normalized concentration changing of MB without catalyst, in presence of ReO_3 -PVP and in presence of ReO_3 -Chitosan (b) Normalized concentration changing of MB ($\ln C/C_0$) vs time for the ReO_3 -Chitosan precursor.

3.2 Photocatalytic behavior of $\text{ReO}_3/\text{SiO}_2$ composites

With the purpose to compare the photocatalytic efficiency of ReO_3 with their composite $\text{ReO}_3/\text{SiO}_2$ the photodegradation of blue methylene was performed. Although the composite $\text{ReO}_3/\text{SiO}_2$ was reported by Rao [8] their photocatalytic activity has been not investigated

with blue methylene neither with another dye contaminant. Figure 8 shows the degradation curve of methylene blue with the composite $\text{ReO}_3/\text{SiO}_2$ from the PSP-co-4-PVP and from the Chitosan polymer precursors. From these curves degradation about 67% and 57 % of degradation in 330 min were found. The degradation kinetic for both composites follow a first order for the composite from PSP-co-4-PVP while that for the Chitosan precursor polymer follow a zero order see Electronic Supporting Material S5. These values are similar to the photocatalytic activity of photocatalytic activity of ReO_3 without their incorporation inside silica. On the other hand, in figure S6 of Supporting Material are showed the absorption spectra vs time of the different oxides.

Fig. 8 Normalized concentration changing of MB without catalyst, in presence of $\text{ReO}_3/\text{SiO}_2$ -PVP (a) and in presence of $\text{ReO}_3/\text{SiO}_2$ -Chitosan (b).

Table 2 summarizes the kinetic data for the degradation of MB with $\text{ReO}_3/\text{SiO}_2$ -PS-4-PVP and $\text{ReO}_3/\text{SiO}_2$ -Chitosan. Due to their no literature report for photodegradation of MB with the ReO_3 and $\text{ReO}_3/\text{SiO}_2$ materials the comparison is not possible. However, some comparison within them can be made. The higher photocatalytic efficient the composite $\text{ReO}_3/\text{SiO}_2$ -PS-4-PVP is in agree with the higher rate constant. With regarding the effect of the SiO_2 matrix on the photocatalytic efficient measured in degradation percentage, the composite $\text{ReO}_3/\text{SiO}_2$ -PS-4-PVP material increases slightly their photocatalytic efficient. Thus, from table 2, the discoloration rate is in agreement with the photodegradation rate for all the materials.

Table 2 Kinetic data for the photodegradation process of MB with ReO_3 and $\text{ReO}_3/\text{SiO}_2$.

Photocatalyst	Photodegradation rate constant k ($10^{-3} \text{M} \cdot \text{min}^{-1}$)	Discoloration rate (%)	R^2 Linear fit (%)
ReO ₃ - PS-4-PVP	2,8	64%	0,977
ReO ₃ -Chitosan	2,8	53%	0,977
ReO ₃ /SiO ₂ -PS-4-PVP	3,7	67%	0,978
ReO ₃ /SiO ₂ -Chitosan	1,9	57%	0,985

3.3 Probable formation mechanism

Some insight about the formation mechanism of the nanostructured Re metal oxides materials from both precursors can be proposed using the mechanism of formation of nanostructured metallic materials from the oligomer precursor $\{\text{NP}(\text{OC}_8\text{H}_{12})_2(\text{OC}_6\text{H}_4\text{PPh}_2\text{-Mn}(\text{CO})_2(\eta^5\text{-C}_5\text{H}_4\text{Me})_2)\}_n$ [24]. A schematic representation of this process is provided in figure 9. Briefly the first step on heating involves the formation of a 3D network to produce a thermally stable matrix. This step is crucial because it offsets the sublimation. The first heating step could involve a cross linking of the Chitosan or PSP-4-PVP polymer giving a 3D matrix containing the ReCl_3 compound linked to the polymeric chain. The following steps could involve the starting of the organic carbonization, producing holes where the nanoparticles begin to nucleate. As it was confirmed in earlier studies [10, 24], the ReO_3 oxide grow over layered graphitic carbon host which is lost near to the final annealing temperature ie. 800 °C.

Fig. 9 Schematic representation of the proposed mechanism of formation of the metal oxide nanoparticles. MX_n represent the general formula of the metallic salt coordinated to the Chitosan polymer and } } } } } } } } represent the polymeric Chitosan. The temperature are referential general values.

4 Conclusions

A general solvent less method using the easily synthesized precursors Chitosan•(ReCl₃)_x and PSP-4-PVP•(ReCl₃)_x affords the nucleation ReO₃ metal oxides. Incorporation of these metal oxides into SiO₂ matrix was achieved using a thermal treatment of the chitosan and PVP precursors to give the ReO₃//SiO₂ composites. Some ReCl₃ present in the ReO₃ was absent in the ReO₃//SiO₂ composite. A regular distribution of the respective nanoparticles inside SiO₂ was observed. For the ReO₃//SiO₂ sample, ReO₃ nanoparticles of about 1 nm were obtained. Photocatalytic degradation of MB using ReO₃ was measured for the first time, founding a high activity. The photocatalytic activity of ReO₃ increase when their incorporation inside SiO₂.
