# JRC SCIENCE FOR POLICY REPORT 

## Scientific, Technical and Economic Committee for Fisheries (STECF)

 $-$Stock Assessments: demersal stocks in the western Mediterranean Sea (STECF-19-10)

Edited by John Simmonds, Alessandro Mannini and Cecilia Pinto

This publication is a Science for Policy report by the Joint Research Centre (JRC), the European Commission's science and knowledge service. It aims to provide evidence-based scientific support to the European policymaking process. The scientific output expressed does not imply a policy position of the European Commission. Neither the European Commission nor any person acting on behalf of the Commission is responsible for the use that might be made of this publication. For information on the methodology and quality underlying the data used in this publication for which the source is neither Eurostat nor other Commission services, users should contact the referenced source. The designations employed and the presentation of material on the maps do not imply the expression of any opinion whatsoever on the part of the European Union concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries.

## TABLE OF CONTENTS

Abstract 12
SCIENTIFIC, TECHNICAL AND ECONOMIC COMMITTEE FOR FISHERIES (STECF) - Stock Assessments: demersal stocks in the western Mediterranean Sea (STECF-19-10) ..... 13
Request to the STECF ..... 13
STECF observations ..... 13
STECF comments ..... 13
STECF conclusions ..... 17
Contact details of STECF members ..... 17
Expert Working GROUP EWG-19-10 report. ..... 22
1 Introduction ..... 23
1.1 Approach to the work ..... 23
1.2 Terms of Reference for EWG-19-10 ..... 23
2 Findings and Conclusions of the Working Group. ..... 25
2.1 Stock-Specific Findings \& Conclusions ..... 26
2.2 Quality of the assessments ..... 28
2.3 Effort data. (ToR 3) ..... 30
3 Follow up items ..... 35
3.1 Length slicing for populations with mid-year spawning ..... 35
3.2 Hake Benchmark ..... 36
4 Basis of the report ..... 36
4.1 Basis of the catch and fishing mortality advice ..... 36
4.2 MSY Reference points for stocks in this report ..... 37
4.2.1 MSY Ranges ..... 37
4.2.2 Values of $F_{\text {MSY }} F_{\text {upp }}$ and Flow ..... 38
4.3 Basis of Short Term Forecasts. ..... 38
5 Summary sheets by stock ..... 39
5.1 Summary sheet for European hake in GSA 1, 5, 6 \& 7 ..... 40
5.2 Summary sheet for deep-water rose shrimp in GSA 1, 5, 6 \& 7 ..... 46
5.3 Summary sheet for red mullet in GSA 1 ..... 52
5.4 Summary sheet for striped red mullet in GSA 5 ..... 59
5.5 Summary sheet for red mullet in GSA 6 ..... 65
5.6 Summary sheet for red mullet in GSA 7 ..... 70
5.7 Summary sheet for Norway lobster in GSA 5 ..... 77
5.8 Summary sheet for Norway lobster in GSA 6 ..... 82
5.9 Summary sheet for European hake in GSA 9, 10 and 11 ..... 87
5.10 Summary sheet for deep-water rose shrimp in GSA 9, 10 and 11 ..... 93
5.11 Summary sheet for red mullet in GSA 9 ..... 99
5.12 Summary sheet for red mullet in GSA 10 ..... 105
5.13 Summary sheet for Norway lobster in GSA 9 ..... 111
5.14 Summary sheet for Norway lobster in GSA 11 ..... 117
5.15 Summary sheet for blue and red shrimp in GSA 1 ..... 121
5.16 Summary sheet for blue and red shrimp in GSA 5 ..... 127
5.17 Summary sheet for blue and red shrimp in GSAs 6 \& 7 ..... 131
5.18 Summary sheet for blue and red shrimp in GSA 9, 10 \& 11 ..... 136
5.19 Summary sheet for giant red shrimp in GSA 9, 10 \& 11 ..... 143
6 Stock Assessments ..... 148
6.1 Hake in GSA 1, 5, 6 \&7 ..... 149
6.1.1 Stock Identity and Biology ..... 149
6.1.2 Data ..... 151
6.1.2.1 Catch (landings and discards) ..... 151
6.1.2.2 Effort. ..... 161

#### Abstract

Commission Decision of 25 February 2016 setting up a Scientific, Technical and Economic Committee for Fisheries, C(2016) 1084, OJ C 74, 26.2.2016, p. 4-10. The Commission may consult the group on any matter relating to marine and fisheries biology, fishing gear technology, fisheries economics, fisheries governance, ecosystem effects of fisheries, aquaculture or similar disciplines. This report is from STECF Expert Working Group 19-10: 2019 stock assessments of demersal stocks in the western Mediterranean Sea from the meeting in Arona Italy from $9^{\text {th }}$ to $15^{\text {rd }}$ September 2019. A total of 19 fish stocks were evaluated. The EWG reports age based assessments and short term forecasts for 15 of the 19 stocks. Catch advice for the other four stocks was based on ICES category 3 evaluations of biomass indices. The content of the report gives the STECF terms of reference, the basis of the evaluations and advice, summaries of state of stock and advised based on either the MSY approach for assessed stocks or the precautionary approach for category 3 based advice. The report contains the full stock assessment reports for the 15 assessments, one full category 3 evaluation and brief re-evaluations and validations of the 2018 results for the final three stocks for which two year's advice was given in 2018. The report also contains the STECF observations and conclusions on the assessment report. These conclusions come from the STECF Plenary meeting November 2019.

## SCIENTIFIC, TECHNICAL AND ECONOMIC COMMITTEE FOR FISHERIES (STECF) - Stock Assessments: demersal stocks in the western Mediterranean Sea (STECF-19-10)

## Request to the STECF

STECF is requested to review the report of the STECF Expert Working Group meeting, evaluate the findings and make any appropriate comments and recommendations.

## STECF observations

The working group was held in Arona, Italy, from 9 to 15 September 2019. The meeting was attended by 16 experts in total, including three STECF members and two JRC experts. One DG MARE representative and one observer also attended the meeting.
The objective of the EWG 19-10 was to carry out demersal stock assessments in the western Mediterranean as defined in the EWG ToRs.

## STECF comments

STECF considers that the EWG addressed adequately all the ToRs. STECF notes that the EWG carefully reviewed the quality of the assessments produced. Some analyses were considered to be suitable for short term forecasts, others were only considered sufficiently reliable to estimate F-status, and for these no forecast was produced.

A total of 19 area/species combinations were evaluated (Tables 5.1.1 and 5.1.2). The EWG has carried out short term forecasts for 15 age-based assessments. Catch advice for four stocks was based on biomass index methods. The main results are summarized in the bullet point list below and in Table 5.1.2. Overall, the assessments indicate that all stocks but two are being significantly overfished, and that biomass is stable at low level or decreasing for the majority of the stocks:

- Hake in GSA 1_5_6_7: the biomass is low/stable. Catches should be reduced by at least 63\% to reach Fmsy in 2020.
- Deep-water rose shrimp in GSA 1_5_6_7: the biomass is increasing. Catches should be reduced by at least $55 \%$ to reach Fmsy in 2020.
- Red Mullet in GSA 1: the biomass is declining. Catches should be reduced by at least $69 \%$ to reach Fmsy in 2020.
- Striped Red Mullet in GSA 5: the biomass is increasing. Catches should be reduced by at least $21 \%$ to reach Fisy $_{\text {ms }} 2020$.
- Red Mullet in GSA 6: the biomass is low/stable. Catches should be reduced by at least 69\% to reach FMSy in 2020.
- Red Mullet in GSA 7: the biomass is stable. Catches may be increased by no more than $31 \%$ to reach Fmsy in 2020.
- Norway lobster in GSA 5: the biomass is fluctuating. Catches should be reduced by at least 47\% to reach Fmsy in 2020.
- Norway lobster in GSA 6: the biomass is low/stable. Catches should be reduced by at least $71 \%$ to reach Fmsy in 2020.
- Hake in GSA 9_10_11: the biomass is declining. Catches should be reduced by at least 63\% to reach FMSY in 2020.
- Deep-water rose shrimp in GSA 9_10_11: the biomass is high/stable. Catches should be reduced by at least 9\% to reach Fmsy in 2020.
- Red Mullet in GSA 9: the biomass has been increasing, though declining in the last year. Catches should be reduced by at least $63 \%$ to reach Fmsy $^{\text {in }} 2020$.
- Red Mullet in GSA 10: the biomass is increasing. Catches should be reduced by at least $23 \%$ to reach FMSy in 2020.
- Norway lobster in GSA 9: the biomass is increasing. Catches should be reduced by at least $34 \%$ to reach $\mathrm{F}_{\text {MSY }}$ in 2020.
- Norway lobster in GSA 11: the biomass is declining. Catches should be reduced by at least $55 \%$ to reach $\mathrm{F}_{\text {msy }}$ in 2020.
- Blue and red shrimp in GSA 1: the biomass is stable. Catches should be reduced by at least 23\% to reach Fmsy in 2020.
- Blue and red shrimp in GSA 5: the biomass is fluctuating. Catches should be reduced by at least $40 \%$ to reach Fmsy in 2020.
- Blue and red shrimp in GSA 6_7: the biomass is fluctuating. Catches should be reduced by at least 65\% to reach FMSy in 2020.
- Blue and red shrimp in GSA 9_10_11: the biomass is declining. Catches should be reduced by at least $81 \%$ to reach $\mathrm{F}_{\mathrm{msy}}$ in 2020.
- Giant red shrimp in GSA 9_10_11: the biomass is declining. Catches should be reduced by at least 71\% to reach $\mathrm{F}_{\mathrm{MSy}}$ in 2020.
STECF considers that for all of the 15 age-based assessments presented in the report, the assessments can be used to provide advice on stock status in terms of $F$ relative to $F_{M s y}$, and to provide catch advice for 2019. STECF notes that the assessments are based on short data series and some degree of uncertainty therefore remain, but STECF considers overall that they provide a robust guidance on the magnitude of changes in F and catches required to reach Fmsy by 2020. The estimates of Flow and Fmsy are considered reasonable estimates that can be expected to be precautionary and STECF considers that they can be used directly. The values for Fupper are indicative only; they have not been evaluated as precautionary and should not be used to give catch advice without further evaluation.

For all the stocks with advice based on abundance index, a precautionary buffer of a $-20 \%$ catch reduction has been applied. STECF notes that this approach is consistent with the procedures applied in the North East Atlantic (ICES stocks). For three of these stocks catch advice for 2020 was already provided in 2018 and is unchanged.

STECF notes that $\mathrm{F}_{\text {MSY }}$ values for red mullet stocks cover a large range (between 0.31 and 0.62 ) in the different GSAs. These differences come partly from the Fbar range which differs across the stocks, but could also be linked to differences in selection parameters, i.e. catch at age structure (particularly for GSA 7), as well as differences in the growth parameters and natural mortality across the different GSAs evaluated. Sensitivity analysis could be performed to fully understand the effect of using different growth parameters on the assessment results.

Norway lobster in GSA 9 is a new assessment with different growth and data treatment from last year. Catch data were improved and extended back to 1994 (against 2003 in previous assessment) in the RECFISH project, and this longer series stabilised the assessment. Catch reporting errors from last year were corrected. This stock has a consistent catch matrix, though the survey is showing poor fit. The estimation of historical exploitation appears more robust than in the most recent years of the assessment.

In contrast, the assessment of Norway lobster in GSA 5 in 2018 looked unstable, and a 2-years advice based on survey index was given.

STECF notes that for deep-water rose shrimp in GSA 1_5_6_7 the MEDITS biomass indices as well as catch are increasing at different rates in the four GSAs; the general trend is mostly driven by GSAs 5 and 6, though the species is showing a sharp increase in biomass also in GSAs 1 and 7, especially in the last year.

Following ToR 3, EWG 19-10 analysed effort data related to demersal fisheries in Western Mediterranean. Issues identified in previous years in the effort data were largely solved, and tables of effort by gear covering majority of fishery were provided. It was also pointed out that fishing effort data analysed at fishing gear level are related to multiple fisheries and multispecies aspects, and not just to the one single species considered in a certain assessment.

STECF notes that data quality deficiencies have been comprehensively addressed by the EWG for each stock in the report. STECF notes that biological and effort data deficiencies have been also reported in the DTMT (Data Transmission Monitoring Tool) and should be addressed and corrected before the next submission.

Table 5.1.1. Summary of work was attempted and basis for any advice. a4a is an age based assessment methods STF is a standard short term projection with assumptions of status quo $F$ and historic recruitment. Index refers to the ICES Category 3 approach to advice for stocks without analytic assessments.

| Area | Species | Previous <br> Analysis (2018) | Attempted analyses and basis of <br> advice |
| :---: | :---: | :---: | :---: |
| $1 \_5 \_6 \_7$ | Hake | a4a | a4a STF |

Table 5.1.2. Summary of advice from EWG $19-10$ by area and species. F 2018 is estimated F in the assessment, and used in the short term forecast for 2019. Change in $F$ is the difference (as a fraction) between target F (Fmsy) in 2020 and the estimated $F$ for 2018. Change in catch is from catch 2018 to catch 2020. Biomass and catch 2016-2018 are given as an indication of trend over the last 3 years for stocks with time series analytical assessments or biomass indices. If the stock is considered to be in a low state or high state due to exploitation rate this is noted too. Biomass reference points are not available for any of these stocks.

| Area | Species | Method/ basis | $F_{\text {bar }}$ range | $\begin{gathered} \text { Biomass } \\ \text { 2016- } \\ 2018 \end{gathered}$ | Catch 20162018 | F 2018 | F 2020 | Change in $F$ | $\begin{aligned} & \text { Catch } \\ & \text { 2018* } \end{aligned}$ | $\begin{aligned} & \text { Catch } \\ & 2020 \end{aligned}$ | $\begin{aligned} & \text { Change } \\ & \text { in } \\ & \text { catch } \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1_5_6_7 | Hake | a4a | 1-3 | low/stable | Stable | 1.84 | 0.38 | -79\% | 3444 | 1268 | -63\% |

| 5 | Blue and red shrimp | Survey Index |  | fluctuating | Stable |  |  |  | 250 | 150 | -40\% |
| 6 -7 | Blue and red shrimp | a4a | 0-2 | fluctuating | Stable | 1.26 | 0.33 | -74\% | 644 | 226 | -65\% |
| 9_10_11 | Blue and red shrimp | a4a | 2-5 | declining | Increasing | 1.45 | 0.39 | -73\% | 387 | 72 | -81\% |
| 9_10_11 | Giant red shrimp | a4a | 1-3 | declining | Increasing | 1.37 | 0.45 | -67\% | 681 | 199 | -71\% |

*Estimated

STECF notes that the Western Mediterranean MAP has the objective of achieving Fmsy either by 2020 or at latest 2025. For a few stocks, $\mathrm{F}_{2018}$ is close to $\mathrm{F}_{\text {msy, }}$ but for many stocks, such as European hake and red shrimps, $F$ is substantially higher than $\mathrm{F}_{\text {Msy }}$ and it seems likely that these
stocks will be considered under the objective for reaching Fmsy by 2025. For such stocks, the MAP does not specify how it is expected that F should change over the 6 years from 2020 to 2025. Currently STECF reports the FMSY and expected catch in the advice year based on EWG assessment and short term forecasts. However, if the approach is to attempt a reduction in F to achieve Fmsy by 2025, it may be helpful to give advice in relationship to such a transition. The Commission may consider if they need transition advice and if so, what transition is to be followed.
In 2010 and the following years, ICES provided advice following an MSY transition approach with a linear change in F from 2010 to achieve $\mathrm{F}_{\text {MSY }}$ in 2015. As an illustration, this approach is updated for transition from 2020 to 2025, and is shown below:
$F_{\text {msytransition }}(2020)=\left\{0.833 \times \mathrm{F}_{2019}+0.167 \times \mathrm{Fmsy}^{2}(2019)\right\}$
whereas for the following years:
Fmsy-transition $(2021)=\left\{0.667 \times \mathrm{F}_{2019}+0.333 \times \operatorname{FMSy}(2020)\right\}$
FMSY-transition (2022) $=\left\{0.500 \times \mathrm{F}_{2019}+0.500 \times \mathrm{Fmsy}^{(2021)}\right\}$
FMSY-transition (2023) $=\left\{0.333 \times \mathrm{F}_{2019}+0.667 \times \mathrm{FmSY}^{(2022)}\right\}$
FMSY-transition $^{(2024)}=\left\{0.166 \times \mathrm{F}_{2019}+0.833 \times \mathrm{F}_{\text {MSY }}(2023)\right\}$
FMSY-transition (2025) $^{2}=\left\{0.000 \times \mathrm{F}_{2019}+1.000 \times \mathrm{F}_{\text {MSY }}(2024)\right\}$
Where for the first year $\mathrm{F}_{2019}=\mathrm{F}_{2018}$, for subsequent years $\mathrm{F}_{2019}$ is the F in 2019 estimated/updated in the subsequent annual assessments and $\mathrm{F}_{\text {MSY }}$ (2019) is the estimate of $\mathrm{F}_{\text {MSY }}$ in 2019 and then updated as $\mathrm{F}_{\text {msy }}(2020,2021$, etc.) in each subsequent estimation of reference points following annual assessments.

## STECF conclusions

STECF concludes that the EWG addressed all the ToRs appropriately.
STECF endorses the assessments and evaluation of stock status produced by the EWG. STECF concludes that the results of the assessments accepted by EWG 19-10 provide reliable information on the status of the stocks and the trends in stock biomass and fishing mortality. One assessment was refused due to inconsistencies between catch and survey data leading to lack of robustness of the assessment. For this stock, advice was given using survey index trend. Survey trends were also used as the basis for advice for other three stocks, consistently with what was done last year.
STECF concludes that the errors reported in the DTMT should be addressed and corrected before the next data submission.

## Contact details of STECF members

${ }^{1}$ - Information on STECF members' affiliations is displayed for information only. In any case, Members of the STECF shall act independently. In the context of the STECF work, the committee members do not represent the institutions/bodies they are affiliated to in their daily jobs. STECF members also declare at each meeting of the STECF and of its Expert Working Groups any specific interest which might be considered prejudicial to their independence in relation to specific items on the agenda. These declarations are displayed on the public meeting's website if experts explicitly authorized the JRC to do so in accordance with EU legislation on the protection of personnel data. ## REPORT TO THE STECF

# EXPERT WORKING GROUP ON <br> Stock Assessments: demersal stocks in the western Mediterranean Sea (EWG-19-10) 

Arona, Italy, 9-15 September 2019

This report does not necessarily reflect the view of the STECF and the European Commission and in no way anticipates the Commission's
future policy in this area

### 1.1 Approach to the work

The working group was held in Arona, Italy, from 9th to 15th Sept 2019. The meeting was attended by 16 experts in total, including three STECF members and two JRC experts. The EWG had one observer who attended part time.

The objective of the Mediterranean Methodology EWG 19-10 was to carry out assessments and provide draft advice for stocks identified in the ToR supplied by STECF. An initial plenary session commenced at 09:30 on the first day. The ToRs were discussed and examined in detail. Stocks were allocated to participants in small groups based on expertise. An ftp repository was created ad-hoc to share documents, data and scripts and prepare the report. The stocks were evaluated by the GSA groups identified in the ToRs.

Plenary sessions were held each day to monitor progress and share results. The overall conclusions for each stock were discussed and finalized in plenary on the last day.

### 1.2 Terms of Reference for EWG-19-10

DG MARE focal persons: Amanda Perez Perera
Chair: John Simmonds

GENERAL GUIDELINES: unless the data used and information provided comes from the official DCF data calls, the experts are requested to indicate the data source from where certain information has been taken (e.g. $L-W$ relationships, prices) or if it is an experts' reasoned guess.

Data collected outside the DCF shall be used as well and merged with DCF data whenever necessary and following quality check. Due account shall also be given to data used and assessments carried out within the FAO regional projects cofunded by the European Commission and EU-Member States in particular when using data collected through the $D C F / D C R$ and $E U$ funded research projects, studies and other types of $E U$ funding.

The raw data used to generate the input data, assessment scripts as well as input files should be made available to the JRC for reproducibility of the assessments and compilation of the STECF stock assessment database (https://stecf.jrc.ec.europa.eu/dd/medbs/ram).

STECF 17-07 ${ }^{1}$ defined methodological guidelines to ensure standardized practices for the preparation of stock assessment input data. EWG 18-12 should adhere to these recommendations referring to the need of: (i) coherence of all growth parameters used in the assessments; (ii) improvement in documenting and defining the growth models and age slicing; (iii) test where possible age slicing by sex;(iv) t0 should be truncated to values between 0 and -0.2 ; and (v) review the raw age length data, where necessary refitting growth models (section 2.2 in the EWG 17-07 report).

1 Scientific, Technical and Economic Committee for Fisheries (STECF) - Methodology for the Stock Assessments in the Mediterranean Sea (STECF-17-07). Publications Office of the European Union, Luxembourg, 2017, ISBN 978-92-79-67479-2, doi:10.2760/106023, JRC107583.

## For the stocks given in the table below, the EWG 19-10 is requested:

ToR 1. To compile and provide the most updated information on stock identification and boundaries, length and age composition, growth, maturity, feeding, essential fish habitats and natural mortality.

ToR 2. To compile and provide complete sets of annual data on landings and discards for the longest time series available up to and including 2018, including length frequency distribution over time.

ToR 3. To compile and provide complete sets of annual data on fishing effort for the longest time series available up to and including 2018. This should be described in terms of fishing days, days at sea, GT*days and nominal effort by Member State, GSA and fishing gear.

ToR 4. To compile and provide indices of abundances and biomass by year and size/age structure for the longest time series available up to and including 2018. Where possible, the EWG should take into account the results of the EU-funded project RECFISH ${ }^{2}$.

ToR 5. To assess trends in historic and recent stock parameters on fishing mortality, stock biomass, spawning stock biomass, and recruitment. Different assessment models should be applied as appropriate, including retrospective analyses. The selection of the most reliable assessment shall be explained. Assumptions and uncertainties shall be specified. To assist with development of management plans, give preference to models that allow estimation of uncertainty, in line with the recommendations of STECF EWG 17-07.

ToR 6. To estimate the $\mathrm{F}_{\text {MSY }}$ point value, range of $\mathrm{F}_{\text {MSY }}$ (i.e. MSY $\mathrm{F}_{\text {LOWER }}$ and MSY $\mathrm{F}_{\text {UPPER }}$ ) and the conservation reference points (i.e. $B_{P A}$ and $B_{\text {LIM }}$ ), or proxy. The proposed values shall be related to long-term high yields and low risk of stock/fishery collapse and ensure that the exploitation levels restore and maintain marine biological resources at least at levels which can produce the maximum sustainable yield.

ToR 7. To provide short and medium term forecasts of spawning stock biomass, stock biomass and catches. The forecasts shall include different management scenarios, including: the status quo fishing mortality and target $\mathrm{F}_{\text {MSY }}$ range (i.e. F $\mathrm{F}_{\text {MSY }}$ point value, MSY $F_{\text {LOwER }}$ and MSY $\mathrm{F}_{\text {UPPER }}$ ) or other appropriate proxy by 2020 and 2025.

ToR 8. To summarize and concisely describe all data quality deficiencies, including possible limitations with the surveys of relevance for stock assessments and fisheries. Such review and description are to be based on the data format of the official DCF data call for the Mediterranean Sea launched on May 2019. Identify further research studies and data collection which would be required for improved fish stock assessments.

ToR 9. To ensure that all unresolved data transmission issues encountered prior to and during the EWG meeting are reported on line via the Data Transmission Monitoring Tool (DTMT) available at https://datacollection.jrc.ec.europa.eu/web/dcf/dtmt. Guidance on precisely what should be inserted in the DTMT, log-on credentials and access rights will be provided separately by the STECF Secretariat focal point for the EWG.

ToR 10. Using the report structure developed in 2018 (EWG 18-12), provide a synoptic overview of: (i) the fishery; (ii) the most recent state of the stock (spawning stock biomass, stock biomass, recruits and exploitation level by fishing gear); (iii) the source of data and methods and; (iv) the management advice, including $\mathrm{F}_{\text {MSY }}$ value, range of values, conservation reference points and effort levels.

[^0]Table 1.1- List of suggested stocks to be assessed by the EWG 19-10.

| Area | Common name | Scientific name |
| :--- | :--- | :--- |
| GSA 1-5-6-7 | Hake | Merluccius merluccius |
| GSA 1-5-6-7 | Deep-water rose shrimp | Parapenaeus longirostris |
| GSA 1 | Red mullet | Mullus barbatus |
| GSA 5 | Striped red mullet | Mullus surmuletus |
| GSA 6 | Red mullet | Mullus barbatus |
| GSA 7 | Red mullet | Mullus barbatus |
| GSA 5 | Norway lobster | Nephrops norvegicus |
| GSA 6 | Norway lobster | Nephrops norvegicus |

| GSA 9-10-11 | Hake | Merluccius merluccius |
| :--- | :--- | :--- |
| GSA 9-10-11 | Deep-water rose shrimp | Parapenaeus longirostris |
| GSA 9 | Red mullet | Mullus barbatus |
| GSA 10 | Red mullet | Mullus barbatus |
| GSA 9 | Norway lobster | Nephrops norvegicus |
| GSA 11 | Norway lobster | Nephrops norvegicus |

| GSA 1 | Blue and red shrimp | Aristeus antennatus |
| :--- | :--- | :--- |
| GSA 5 | Blue and red shrimp | Aristeus antennatus $(*)$ |

| GSA 9-10-11 | Giant red shrimp | Aristaeomorpha foliacea |
| GSA 9-10-11 | Blue and red shrimp | Aristeus antennatus |

(*) Explore the possibility to merge blue and red shrimp in GSAs 5-6-7.

## 2 Findings and Conclusions of the Working Group

A total of 19 area/species combinations were evaluated. The EWG has carried out and accepted 15 age based analytical assessments with short term forecasts, $F$ target and catch advice for 2019. Fourteen of these were for the same stocks as last year, and one was a stock for which
index advice had previously been given. Of the 4 remaining stocks index evaluations with catch advice are provided, three are taken from last year's report, for these stocks the survey time series and catches were examined and found to be consistent with the data analysed last year, so the advice from last year was considered valid (Nephrops in GAS 11 Blue and red shrimp GSA 5, and Deep Water Rose Shrimp GSA 1, 5, 6 \& 7) the results are considered fully acceptable. Last year the EWG evaluated four Nephrops stocks and considered that two could be assessed with an age based assessment and two could not, of these four two follow the same outcome (Nephrops 6 and Nephrops 11) For the other two; Nephrops in GSA 5 STECF accepted the assessment in 2018 but the instability in the assessment found this year suggested it would be preferable to give index advice. For Nephrops in 9 there was an extensive revision and extension of the data and the revised data gave good coherence in the cohorts in the catch, and it's proposed that the assessment should now be accepted.

### 2.1 Stock-Specific Findings \& Conclusions

See the stock specific summary sheets (section 5) for the main details by stock, and the assessments (Section 6) for full details. This section provides collated information on methods and stock status. The methods tested and chosen by stock are provided in Table 2.1. Where possible age based assessments are used, where these do not provide stable enough models, if indices of abundance are available ICES category 3 stock advice is applied. The results in terms F and catch and relative changes from 2018 to 2020 are provided in Table 2.2.

Table 2.1 Summary of work was attempted and basis for any advice. A4A is an age based assessment methods STF is a standard short term projection with assumptions of status quo F and historic recruitment. Index refers to the ICES Category 3 approach to advice for stocks without analytic assessments.

| Area | Common Species name | 2018 STECF | 2019 Assess |
| :--- | :--- | :--- | :--- |
| $1 \_5 \_6 \_7$ | Hake | a4a | a4a STF |
| $1 \_5 \_6 \_7$ | Deep-water rose shrimp | Index | 2018 Index |
| 1 | Red Mullet | a4a | a4a STF |
| 5 | Striped Red Mullet |  | a4a STF |
| 6 | Red Mullet | a4a | a4a STF |
| 7 | Red Mullet | a4a | a4a STF |
| 5 | Norway lobster | a4a | Index (2019) |
| 6 | Norway lobster | a4a | a4a STF |
| $9 \_10 \_11$ | Hake | a4a | a4a STF |
| $9 \_10 \_11$ | Deep-water rose shrimp | a4a | a4a STF |
| 9 | Red Mullet | a4a | a4a STF |
| 10 | Red Mullet | a4a | a4a STF |
| 9 | Norway lobster | Index | a4a STF |
| 11 | Norway lobster | Index | 2018 Index |
| 1 | Blue and red shrimp | a4a | a4a STF |
| 5 | Blue and red shrimp | Index | 2018 Index |
| $6 \_7$ | Blue and red shrimp | a4a (6 only) | a4a STF |
| $9 \_10$ | Blue and red shrimp |  | a4a STF |
| $9 \_10 \_11$ | Giant red shrimp | a4a | a4a STF |

Table 2.2 Summary of advice from EWG 19-10 by area and species. F 2018 is estimated $F$ in the assessment, and used in the short term forecast for 2019. Change in $F$ is the difference (as a fraction) between target $F$ in 2020 and the estimated $F$ for 2018. Change in catch is from catch 2018 to catch 2020. Biomass status is given as an indication of trend over the last 3 years for stocks with time series analytical assessments or biomass indices. If the stock is considered to be in a low state or high state due to exploitation rate this is noted too. Biomass reference points are not available for any of these stocks.

### 2.2 Quality of the assessments

## Hake:

For hake in GSA 9-11 the same model was used as last year, with smoothing parameter changed to account for an additional year of data. There were no major issues and a relatively simple model fitted well with comparable results between years. For hake in GAS 1-5-6\&7 the information on catches indicated changes in the early part of the time series. The catchability model from last year gave unstable outcomes and was replaced by a logistic function. As with last year all simple model fits to this data gave considerable instability so as with last year model complexity was increased, and some smoothing introduced. The resulting model is considered adequate, but is more uncertain (due to complexity) than for the other hake area, estimated of $F$ are similar though the reduction in terminal F last year is not seen this year. Both assessments were considered suitable for STF advice.

## Red Mullet:

For GSA 1 the model was rather unstable and revised data has resulted in a different perception of stock with F closer to $\mathrm{F}_{\mathrm{MSY}}$. The assessment is considered suitable for STF but it is noted that there are some concerns and this is a marginal assessment.
For GSA 6 the assessment was relatively stable, with different data treatment but with very similar perception of the state of the stock compared to last year.
GSA 7 was very similar to last year's assessment the only difference was use of a different Fbar which now excludes age 0 which had no catch following the revision of data treatment.
GSA 9 was more stable assessment than last year revised data treatment with very similar perception of exploitation rate.
For GSA 10 some catches were revised and assessment is more stable than previously, for this stock growth are consistent with mid-year spawning and with same data treatment as last year $F$ is still considered below Fmsy.

## Striped Red Mullet in GSA 5.

This is a new assessment. The historic part of the assessment appears relatively stable with increasing SSB and decreasing $F$ in recent years. While the data supports increases in stock and catch, the extent of the decline in $F$ is less certain. It was noted that MEDITS contained a very high uncertain value in 2017 and the model was parameterised to using variance weighting to reduce the influence of that point. Overall while the historic part of the model is stable the conclusion on reducing $F$ in last years is not seen in XSA assessments. The age based assessment presented is consistent with SPICT assessment from RECFISH.

## Nephrops

Nephrops 5 data treatment, model was uncertain last year but this year appears very unstable. While there are some minor data issues, these were largely resolved. Different F and Q models were tested and including with and without smoothing. It was judged that the model was not suitable for advice and advice was based on ICES category 3 approach using the MEDITs survey index.
Nephrops in 6 gave a relatively stable assessment. The same model as last year with revised data treatment. Reference points were largely unchanged though $F$ is higher, due to change of age range.

Nephrops 9 is a new assessment with different growth and data treatment, this stock has a consistent catch matrix though the survey is noisy with correlated residuals therefore with a potential for consistent errors of consecutive years. It was concluded that stock status appear robust along the series, though uncertain in the end of the assessment, and in conclusion exploitation historically appear robust, and is estimated to be recently below $\mathrm{F}_{\text {MSY }}$ but above again in 2018.

Nephrops 11 The survey and catch data inspected advice from last year is considered applicable.

## Deepwater Rose Shrimp

GSA $1,5,6,7$ The survey and catch data inspected advice from last year is considered applicable.

GSA 9, 10, 11 some differences were observed from last year, the assessment it was necessary to introduce smoothing at older ages 2 and 3 in fishery. The assessment may be more unstable but is considered more realistic accounting better for growth. The stock is now considered close to $F_{M S Y}$, and is more in line with assessments from earlier years than the one in 2018.

## Red Blue Shrimp.

GSA 1 Different data treatment was used this year but this did not influence the conclusion of the assessment relative to reference. The time-series is short and there are issues with retrospective suggesting an unstable assessment overall. The current assessment is in line with 2018 assessment with age range on F modified to deal with observed age range better.

GSA 6-7 this is a new assessment. There was uncertainty with choice of growth function. The data treatment last year resulted in anomalous appearance of 0 group in MEDITS and in catches. Several data treatments and assessments tested. Some differences in estimated and reported catch were noted. More exploration is needed to determine the most appropriate growth functions. All models indicate that the stock is overexploited, with similar F/ FMSy for treatments. So the influences of the different options on F advice are more minor.

GSA 9, 10, 11 the growth parameters for this area do not result in anomalous age zero values and models were applied directly. A new assessment with relatively simple model different models parameterisations was tested but conclusions were robust to alternative setting and final chosen on statistical criteria.

Giant Red shrimp GSA 9_10_11

This was an update assessment with minor changes to growth model. Catches were split by sex as in 2018 but new sex ratio data for GSA 11 allowed each GSA to be split separately. The conclusions of the assessment are in line with last year. Catches show good internal consistency, with more noise in the survey. Overall the assessment appears stable.

### 2.3 Effort data. (ToR 3)

ToR 3. To compile and provide complete sets of annual data on fishing effort for the longest time series available up to and including 2018. This should be described in terms of fishing days, days at sea, GT*days and nominal effort by Member State, GSA and fishing gear.

In accordance with ToR 3, EWG1910 analysed effort data (file: effort.csv) related to demersal fisheries in Wester Mediterranean (GSAs: 1, 5, 6, 7, 9, 10 and 11). Following suggestion of Commission representative, EWG1910 allocated the most of time to analyse effort data related to Fishing days as principal effort index.

Effort data in DCF database (data file: effort.csv) related to Western Mediterranean (GSAs 1, 5, 6, 7, 9, 10 and 11), as available to EWG1910, consisted of 15,320 records in total, in period 20022018. These data were submitted by four EU Member states (ESP, FRA, ITA and MLT), indicating fishing effort performed by 23 different gear types, as well as by unknown gear (Non available data: gear code -1).
Among total number of effort data records (15,320), approximately $13 \%$ of effort data (1940 records) are related to unknown gear type (Fig 2.3.1). These records without gear data were reported by Spain ( 335 records in 2002-2008 period), France (145 records in 2015-2018 period) and Italy ( 1460 records in 2002-2018 period).

Figure 2.3.1. Amounts of available effort data records with and without information on the gear.

Consequently, 13,380 out of 15,320 records of effort data, related to 23 different gears, were used in further effort data analyses., After examining the catches gear by species by GSA the EWG decided to take into account following gears for species concerned covering the high $90 \%$ s of the catch.
It has been realized that effort data are not species specific, but refers to different GSAs, gears, fisheries, countries, etc. With aim to associate effort data with particular stock assessments, based on local expert knowledge, EWG1910 made a selection of gear types in different GSAs (Table 2.3.1). The principal gear included in all fisheries was Bottom otter trawl (OTB).

Table 2.3.1. Gears types as related to different assessments.

| Assessment / GEAR types | GNS | GTR | LLS | OTB |
| :---: | :--- | :--- | :--- | :--- |
| Blue \& red shrimp (GSA 1) |  |  |  |  |
| Blue \& red shrimp (GSA 5) |  |  |  |  |

| Norway lobster (GSA 11) |  |  |  |  |
| Note: * - GNS considered in GSA 10 only |  |  |  |  |

However, EWG19-10 also highlights that these gears indicated in the table are used in framework of different fisheries where multispecies catches are obtained. So, it is important to keep in mind that fishing effort data, that according to ToR is analysed on fishing gear level, are related to multiple fisheries and multispecies aspects, and not just to the one single species considered in the assessments.

Despite instructions given in Annex 1 of 2019 Med \& BS Data call, all countries report Area code as SA instead GSA. Fishery codes DEMF and FIN, reported by FRA ( 25 records in 2015, 2016 and 2017 data) are not currently in use also. All countries report area as SA and not GSA as indicated in Annex 1 of 2019 Med \& BS Data call. EWG19-10 also noted small difference in area reporting between MLT and ITA, namely for GSA 11 MLT reports SA 11.1 or 11.2 , while ITA reports SA 11. These findings had no any effect on data use by EWG19-10, and therefore are not considered as data issues.

However, lack of effort data from France (FRA) for the period before 2015 has been considered as a very serious issue, preventing EWG19-10 to make complete estimation of fishing effort in the areas where fishing fleet from France is operating. EWG19-10 realized that lack of FRA effort data for the period before 2015 were noted before (see DTMT record Id 3290) and missing data was already requested from France (see DTMT), but these data are still not submitted and thus not available to EWG19-10. Member state (FRA) replied to this data issue, but following DTF assessment (record no. 3290) STECF find that answer provided by MS is unsatisfactory. No comment/action on that issue is given from DG-MARE.
EWG19-10 also investigated previous data issue concerning biased effort data in GSA 9 and 10 (Id 3268). This data issue was about biased/unreliable effort data in which number of reported fishing days exceeded the maximum number of days in one quarter (i.e. $>90$ days/quarter). Member state (ITA) replied to this data issue, but following DTF assessment (DTMT record no. 3268) STECF find that answer provided by MS is unsatisfactory. No comment/action on that issue is given from DG-MARE. However, EWG19-10 noted that most of biased data from ITA have been corrected, and just 13 records from 2004, concerning demersal fisheries, still remained uncorrected in GSA 9 and 10 (Table 2.3.2).

Table 2.3.2. A few remained uncorrected data records in GSA 9 and 10 from 2004.

During analyses of records related to demersal fisheries in area GSA 5 (Balearic Islands) it had been expected to have information on fishing efforts from Spanish (ESP) vessels only. However, France (FRA) and Malta (MLT) also reported their fishing activities in area GSA 5 (Table 2.3.3.).

Table 2.3.3. Fishing effort data in GSA 5 as reported by France and Malta.

EWG19-10 observed unexpected pattern of fishing effort data from Spain (ESP) related to trammel nets fishing activities in Balearic Islands (GSA 5), indicating significant decrease in 2007 and 2008 years. It is suspected that 2007 and 2008 data might be biased, and it will be advisable that MS concerned check these data records (Table 2.3.4).

Generally, in most of GSAs analysed, fishing effort in terms of fishing days has decreasing trend. However, EWG19-10 also observed an unexpected strong increase in number of fishing days in 2018 related to bottom otter trawls (OTB) fleet operating in area GSA 11 (Sardinia) in comparison to previous years. Results of following more detailed analyses indicated that the reason for that is large increase in reported number of fishing vessels that used OTB fishing gear in GSA 11.
EWG19-10 emphasizes the fact that from effort dataset it is not possible to derive exact information on number of fishing vessels. So, the analyses made included the sum of no. vessels reported in all quarters ( $1,2,3$ and 4 ), as well as analyses of maximum number of vessels reported by quarter and by
vessel sizes within 2004-2018 period (Fig 2.3.2 and Fig 2.3.3), are intended to be used just as indications. EWG suggests further analyses of real number of fishing vessels using bottom otter trawls (OTB) in Sardinia (GSA 11) to be performed by STECF.

Figure 2.3.2. Sum of no. vessels using OTB gear in GSA 11 as reported in all quarters (1, 2, 3 and 4).

Figure 2.3.3. Maximum no. vessels using OTB gear in GSA 11 as reported by quarter and by vessel sizes.

Finally, in order to better link effort to fisheries, EWG19-10 began to evaluate the relations species vs. gear $\&$ fishery data more in detail in landing data table, and some odd records were noted. For example, in 24 data records hake (HKE) appears as a catch obtained by drifting longline gear (LLD) used in large pelagic fishery (LPF) in GSA 10, that are considered as inconsistent data records. Also, some inconsistencies in few records in terms of gear vs. fishery data entries were noticed, as use of bottom otter trawl (OTB) in small pelagic fishery (SPF) or use of drifting longlines (LLD) in demersal fishery (DEMF). These inconsistent data records are shown in Table 2.3.5. Due to these issues the metier / fishery link was not explored further.

In addition to analyses of effort data (fishing days) of particular gear types related to different stock assessments, EWG19-10 also provides in Report the most complete sets of annual data on fishing effort for the longest time series available. Tables describing fishing days, days at sea, GT*days and nominal effort by Member states, GSAs and fishing gear are given in Annex B. It is noted that for some areas and some countries 'Days at Sea' data and 'Fishing Days' data are numerically equal.

## 3 FOLLOW UP ITEMS

### 3.1 Length slicing for populations with mid-year spawning.

In last year's report attention was drawn to the issue of correctly assigning length to age through length slicing routines such as L2A. It was noted that it was important that the size at which the age transition occurs needs to be checked, so that numbers at length caught are mapped appropriately to age with the age changing 1st of January consistent with calendar year assessments used to give calendar year advice. Often growth curves are developed to give size at age from the nominal birth date of the individuals. When spawning occurs in winter there is a coincidence of birth date and calendar year and it should be expected that growth is referred to 1st January. However, if spawning is mid-year, 1st July, then growth may be defined from 1st July or may still be on a calendar year basis depending on how the data and methods used to give growth curves. All of the stocks except hake in this assessment WG are considered to have a summer spawning peak, and the spawning biomass is calculated for 1st of July. In order to check the veracity of the functions used for slicing length to age the growth points defined by the selected growth curves at 6 months, 1 year and 18 months were compared with MEDITS surveys modes and expected presence or absence of 0 group individuals, given that generally 0 group should only be observed in significant numbers in the Autumn. In January through May-June 0 group should be rare. In many cases the 12 month point on selected growth curves was found to coincide with sizes expected at spawning time. In the case of summer spawning stocks and calendar year assessment it is necessary that age 1 individuals are those from month 7 to month 18 , and age 2 from month 19 to 30 etc. In using L2A the required shift (from 12/24/36 month to $6 / 18 / 30$ months) is easily obtained by shifting to by 0.5 just for the L2A slicing.

The growth parameters are used not only for length to age slicing, but also to obtain estimates of natural mortality. A brief examination of the natural mortality methods used in the group showed that it's important to use the true to value in the equations for natural mortality as this influences $M$ in the first year in a more complex way. Changing t0 changes the natural mortality incorrectly. However, the values of $M$ derived then relate to a full years mortality at each age whereas the 0 group are subject to only 6 months mortality but the magnitude of the mortality should be higher, suitable for only the smallest sizes. The consequences of this are twofold. Recruitment is artificially elevated to replace the numbers lost through the excess mortality; this is a minor technical issue which is not thought to be of major significance. However, the value of $M$ particularly at age 0 but to some extent at age 1 is sensitive to the parameterisation. In some stocks this appears to have little impact (Giant red shrimp in GSA 9_10_11) but on others (Blue and red shrimp in GSA 1 and DWRS in GSA 9_10_11) the effect on $\bar{F}_{0.1}$ is more important. For species such has herring or mackerel with summer or autumn spawning, assessed by ICES using annual calendar year models it is normal practice to use annual mortality. It's currently unclear what is the correct way to deal with this issue. More work is required to check the best way to parameterise M in an annual model with mid-year spawning. One solution if the data is available is to consider a model with 6 month or quarterly time steps. However, the quality of the data required to parameterise such model is lacking in some cases, and quarterly data was not available at the meeting. The group concluded it was advisable to follow ICES practice and keep annualised mortality for age 0 .

For most assessments (red and blue shrimp in GSA 1 and DPS in GSA 9, 10 and 11) the effect of advice was negligible. For others the issues were more complex. The assessment of blue and red shrimp in GSAs 6 \& 7 showed some discrepancies related to the method of slicing LFD data. Length slicing has been a topic of considerable uncertainty and debate for many years The STECF EWG suggest that in future the possible methods of slicing LFD data (of fishes and invertebrates),
as well as growth information they are using, are thoroughly reviewed, taking into consideration the seasonality of growth, reproduction and moulting processes, in order to define and ably the best practice in cohort slicing for stock assessment. This is particularly the case for the red and blue shrimps and red mullet where different growth is used and length slicing can give different results.

### 3.2 Hake Benchmark

GFCM is proposing a benchmark for hake in the Mediterranean Sea (excluding Adriatic) December 2019. The EWG briefly considered the work required and made the following notes, these related to hake in GSAs $1,5,6,7,9,10$ and 11.

The choice of stock boundaries by GSA will need examination; there are four concepts for consideration in this approach, available knowledge on spatial separation of spawning/stock; Differences in dynamics across areas; improvement/deterioration of estimation by joining/separating areas; utility of management information across areas. Taking account also of data availability for types of models.

Availability of data for main parameterisation, availability of age length relationships, use of otolith directly or to inform growth equations. Ensuring coherence of mean weight and fraction mature with growth. Separation by sex for both growth and maturation, and assembling data to examine this. Selection of best time assignment for spawning time (January?) and appropriate stock weights for this spawning time.

If there is to be a continued use of deterministic length slicing and spawning is concentrated substantially in one period of the year then improvements might be possible by slicing quarterly catch data and surveys explicitly based on their temporal placement (i.e. setting age slicing boundaries at the growth points 6 months before and after survey and 6 months before and after the centre of the quarterly data.

## 4 BASIS OF THE REPORT

### 4.1 Basis of the catch and fishing mortality advice

The summary sheets by stock, provided in Section 5 contain catch advice. The basis of this advice depends on the type and quality of information available from the analyses and is as follows:

1) Full assessment and full MSY reference points or with surplus production model with $F$ and biomass relative to F and $\mathrm{B}_{\text {msy: }}$ : Catch advice at MSY based on short term forecast. Not used.
2) Full assessment without full evaluation MSY reference points due to short time historic series: Catch advice based on MSY proxy of $\mathrm{F}_{0.1}$ based on short term forecast. Used for all a4a assessments
3) Assessment providing SSB tend information historic $F$ evaluation, not suitable for STF Catch / Effort advice under precautionary considerations (Patterson 1992) F= FMSY with Harvest Rate (HR) based estimated SSB in most recent year. Not used.
4) For sparse data with insufficient years for VPA type analysis, but with catch at length or age for most of the fishery: advice is based on pseudo cohort analysis at equilibrium, with estimate of current $F$ relative to $\mathrm{F}_{0.1}$. Not used.
5) Trend based indicator with exploitation and stock status know to be OK: Catch / Effort advice under precautionary considerations based on ICES smoothed index of trend without precautionary buffer, giving 2 years advice. Not used.
6) Trend based indictor: Catch / Effort advice under precautionary considerations based on ICES smoothed index of trend with precautionary buffer ( $20 \%$ reduction) Used for 1 stock this year and for $\mathbf{3}$ from last year.
7) Valid length analysis: statement of stock status, indication of direction of change required.
8) No valid analysis: no advice. Not needed

Section 6 contains the main input data and assessment results for this report.

### 4.2 MSY Reference points for stocks in this report

For all of the stocks evaluated in this assessment meeting, the number of years of S-R data is very limited and it is not possible to carry out full evaluations of MSY, because the stock - recruit relationships cannot be established.

Following STECF decision in the absence of full MSY evaluations, and/or biomass reference points STECF considers that $\mathrm{F}_{0.1}$ forms a good proxy for MSY. Thus for all stocks here with analytical assessments $\mathrm{F}_{0.1}$ has been evaluated based on the stock conditions over the last three years. MSY advice in terms of F and catch for 2019 are based on this approach.

### 4.2.1 MSY Ranges

The EWG has been requested to provide MSY ranges for the stocks considered by the EWG. The usual procedure used by ICES would be to establish S-R functions and to evaluate the ranges using this method, constraining the upper interval to be precautionary. As discussed above it has not been possible to establish such relationships for these stocks, either because the data series are too short.

To evaluate MSY ranges for stocks in this report the EWG uses the values of $F$ associated with $\mathrm{F}=\mathrm{F}_{0.1}$ which are given in Table 2.2. These are the $\mathrm{F}_{\text {mS }}$ values from the most updated assessments carried out on Mediterranean stocks assessment. Those values were then used in the formulas provided by STECF EWG 15-06 (STECF, 2015) to derive Fmsy range (Flow and Fupp). The empirical relationships used to estimate FMSY range are the following:
$F_{\text {low }}=0.00296635+0.66021447 \times \mathrm{F}_{0.1}$
$F_{\text {upp }}=0.007801555+1.349401721 \times \mathrm{F}_{0.1}$
where $\mathrm{F}_{0.1}$ is a proxy of $\mathrm{F}_{\text {msy }}$.

None of these methods add information on the precautionary nature of the Fmsy ranges; the values of Fupp and Flow. In the case of stock based on F0.1 the Fmsy is considered to be precautionary, and because Flow is a lower exploitation rate this is will also be precautionary. As the WG is unable to parameterise stock recruit models and does not currently have Blim reference values, it has not been possible to evaluate Fupp, until further evaluations can be completed should not be used for exploitation, and should be replaced with Fmsr.

### 4.2.2 Values of $F_{M S Y} F_{\text {upp }}$ and Flow

The values of $F_{0.1}$, Fupp and Flow are calculated in the assessment sections Section 6 by species. The values are given in the short term forecast table in the stock assessment sections. These are reproduced in the table in Section 5 but with the Fupp value replaced with $\mathrm{F}_{0.1}$. This approach conforms to the one used by ICES (ICES 2014, ICES 2015)

### 4.3 Basis of Short Term Forecasts

The objective of the short term forecast is to provide the best estimate of catch in year $Y+1$ based on the assessment with final year $y-1$. This is then to predict 2 years forward for a range of catch options based on range of $F$ options. The F option that corresponded to MSY approach or precautionary approach (see section 2.1) is then presented as advice. The basis of short term forecasts is as follows:-

- Biological conditions are assumed to be recent biological conditions

This is mean Maturity, Natural Mortality(M), Fraction M and F before spawning from the last three years of the assessment. In many cases there are constant.

- Recruitment - Most probable recruitment
- If recruitment trend occurs ---- Recent recruitment is selected ... Arithmetic Mean of recent years ... at least 3 years
- If no trend occurs expected value...................Geometric mean of series
- Fishery is assumed to be the same as the recent fishery

Fishery selection is assumed to be recent averages over the last three years

- $F$ in intermediate year ---- is assumed to be $F$ status quo
- If $F$ is fluctuating ( $F_{y-2}$ outside $F_{y-1}$ and $F_{y-3}$, or $F_{y-2}=F_{y-3}$ ) - mean of 3 years
- $F$ trend - ( $F_{y-2}$ between $F_{y-1}$ and $F_{y-3}$ or $F_{y-2}=F_{y-1}$ ) - $F$ last year of assessment

## 5 SUMMARY SHEETS BY STOCK

ToR 10. Using the report structure developed in 2018 (EWG 18-12), provide a synoptic overview of: (i) the fishery; (ii) the most recent state of the stock (spawning stock biomass, stock biomass, recruits and exploitation level by fishing gear); (iii) the source of data and methods and; (iv) the management advice, including $F_{M S Y}$ value, range of values, conservation reference points and effort levels.

### 5.1 Summary sheet for European hake in GSA 1, 5, 6 \& 7

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.38 and corresponding catches in 2020 should be no more than 1269 tons.

## Stock development over time

Catches and SSB of European hake show a decreasing trend from 2009 to 2016, with a slight increase in 2017 and 2018. The assessment shows a decreasing trend in the number of recruits in the time series, with the minimum value reached in 2014. Fbar $(1-3)$ shows a sharp increasing to 2010 with a slight upward trend through to 2018 when estimated $F$ is 1.84 as mean of last three years.

Figure 5.1.1 European hake in GSAs 1, 5, 6 and 7: Trends in catch, recruitment, fishing mortality and SSB resulting from the a4a model.

## Stock and exploitation status

The current level of fishing mortality (1.84) is 4.8 times above the reference point $F_{0.1}$, used as a proxy of $\mathrm{F}_{\text {MSY }}(=0.38)$.

Table 5.1.1 European hake in GSAs 1, 5, 6 and 7: State of the stock and fishery relative to reference points.

| Status | 2016 | 2017 | 2018 |
| :---: | :---: | :---: | :---: |
| $F / F_{M S Y}$ | $F>F_{M S Y}$ | $F>F_{M S Y}$ | $F>F_{M S Y}$ |

## Catch scenarios

## Basis of the advice

Table 5.1.4 European hake in GSAs 1, 5, 6 and 7: The basis of the advice.

| Advice basis | F MSY |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

Commercial catches showed better internal consistency than MEDITS survey index. The historic assessment is stable, although assessment model was modified to get an improved fit, this change did not change the historical estimation of $F$. The retrospective analysis showed a strong change in the estimation of $F$ from the previous year, but the $F$ estimated for 2017 is consistent with the $F$ estimated by last year assessment. Also the estimation of recruitment is consistent
with the ones obtained from last year assessment. All the diagnostics were considered acceptable.

## Sources and references

STECF EWG 19-10

### 5.2 Summary sheet for deep-water rose shrimp in GSA 1, 5, 6 \& 7

## STECF advice on fishing opportunities

Based on precautionary considerations, STECF EWG 18-12 advises to decrease the total catch to $96 \%$ of the average 2015-2017 catches equivalent to catches of no more than 638.4 tons in each of 2019 and 2020 implemented either through catch restrictions or effort reduction for the relevant fleets.

## Stock development over time

The relative change in the estimated SSB was used to provide an index for change (Figure 5.2.1). The stock appears to have been quite stable from 2003 to 2014. In the last 3 years the stock has increased rapidly. Based on the index value in the last two years relative to the previous three years the increase in SSB is estimated to be 3.2 times.

SSB trend

Catches

Figure 5.2.1 Deep water rose shrimp in GSA 1, 5, 6\&7: Summary of the MEDITS stock indicator and catch by year.

## Stock and exploitation status

The stock status both in terms of SSB and exploitation rate (F) is unknown. However, the index of SSB shows a rapid increase in abundance over the last 2 to 3 years.

## Catch scenarios

The advice on fishing opportunities for 2019 and 2020 is based on the recent observed catch adjusted to the change in the stock size index The SSB index used to provide the catch scenarios is the mean of the SSB values coming from the $a 4 a$ and XSA assessments, which are accepted for trends. The change is estimated from the two most recent values relative to the three preceding values (see table 5.2.1). The precautionary buffer of $20 \%$ is applied because the precautionary status of the stock is not known.

Table 5.2.2 Deep water rose shrimp in GSA 1, 5, 6\&7: Assumptions made for the interim year and in the forecast. *

|  | applied |  |  |  |
| :--- | :--- | :--- | :---: | :---: |

* The figures in the table are rounded. Calculations were done with unrounded inputs and computed values may not match exactly when calculated using the rounded figures in the table.
** (average catch $\times$ index ratio)
*** catch advice $\times$ ( 1 - discard rate)
$\wedge$ Advice value 2019 relative to advice value 2018.

## Basis of the advice

Table 5.2.3 Deep water rose shrimp in GSA 1, 5, 6\&7: The basis of the advice.

| Advice basis | Precautionary Approach |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

The values of F at age from the a4a assessment show extremely high values for ages 1,2 and 3.
The catchability at age from the XSA assessment was not deemed acceptable. Therefore, the EWG 18-12 concluded that the output of these model were not suitable to provide the basis of the current status of the stock but could be used as indicative of a trend.

## Issues relevant for the advice

Both estimated abundance and biomass indices from MEDITS show similar trends in GSAs 5-6-7, with a sharp increase in the last year. In GSA 1 the trend is more variable throughout the time series and does not show a sharp increase in the last years. Therefore, the advice should be more precautionary for GSA 1.

### 5.3 Summary sheet for red mullet in GSA 1

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that, when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.54 and corresponding catches in 2020 should not exceed 53.5 tonnes.

## Stock development over time

The SSB shows a decline during the past three years with a mean value of 247 tonnes, having the reached a maximum in 2016. The recruitment also shows a sharp declining pattern since the maximum 2016. Catch shows a fluctuating pattern until 2015. In 2014 - 2017 shows an increasing pattern which falls in the last year, close to long term mean.

Figure 5.3.1 Red mullet in GSA 1. Summary of assessment results. Trends in recruitment (in 1000), spawning stock biomass (tonnes), catch (tonnes) and fishing mortality for ages 1 - 3 .

## Stock and exploitation status

The current level of fishing mortality $F_{\text {curr }}(=2.10)$ is larger than the reference point $F_{0.1}$ used as proxy of $\mathrm{F}_{\mathrm{MSY}}(=0.54)$, indicating over exploitation of Red mullet in GSA 1.

## Basis of the advice

Table 5.3.5 Red mullet in GSA 1: Stock The basis of the advice.

| Advice basis | F MSY |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

The retrospective of the assessment shows it is quite stable and the stock status is unaffected by the addition of new data, $F$ is estimated to be well above $F_{\text {MSY }}$ in all years.

Figure 5.3.2 Red mullet in GSA 1: Historical assessment results (final-year recruitment estimates included). (Retrospective graph)

Incorrect length frequency distribution were supplied for the landings data in 2012 these were corrected and used in the assessment. The year 2011 was missing, and 2006 length frequency was misreported, from MEDITS survey. Age slicing method was modified this year to account for mid-year spawning.

## Issues relevant for the advice

No additional relevant issues for the advice.

## Sources and references

STECF EWG 19-10

### 5.4 Summary sheet for striped red mullet in GSA 5

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.42 and corresponding catches in 2020 should be no more than 110.2 tons.

## Stock development over time

Catches and SSB of striped red mullet showed an increasing trend for the last year. Recruitment showed the minimum value for the time series in the last year, after a maximum in the previous year. FBAR1-2 showed a clear decreasing trend in last two years.

Figure 5.4.1 Striped red mullet in GSA 5: Trends in catch, recruitment, fishing mortality and SSB resulting from the a4a model.

## Stock and exploitation status

The current level of fishing mortality is below the reference point $\mathrm{F}_{0.1}$, used as proxy of $\mathrm{Fmsy}^{\text {m }}$ (=0.42).

Table 5.4.1 Striped red mullet in GSA 5: State of the stock and fishery relative to reference points.

## Basis of the advice

Table 5.4.4 Striped red mullet in GSA 5: The basis of the advice.

| Advice basis | FMSY |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

Both catches and survey indices showed good internal consistency. The retrospective analysis run on the a4a model showed consistent results with exception of recruitment which is poorly estimated in the last year. All the diagnostics were considered acceptable.

Figure 5.4.2 Striped red mullet in GSA 5: Historical assessment results (final-year recruitment estimates included). (Retrospective graph)

## Sources and references

STECF EWG 19-10

### 5.5 Summary sheet for red mullet in GSA 6

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.31 and corresponding catches in 2020 should be no more than 448 tons.

## Stock development over time

Catches of red mullet show an increasing trend in the last years and SSB and recruitment reached a maximum in 2016, decreasing in 2017 and 2018. F has been high and stable from 2010, slightly increasing in 2018.

Stock Summary

Figure 5.5.1 Red mullet GSA 6: Trends in catch, recruitment, fishing mortality and SSB resulting from the a4a model.

## Stock and exploitation status

The current level of fishing mortality is above the reference point Fo.1, used as proxy of Fmsy ( $=0.31$ ).

### 5.6 Summary sheet for red mullet in GSA 7

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.62 and corresponding catches in 2020 should not exceed 364 tonnes.

## Stock development over time

Red mullet in GSA 7 shows an increasing trend in catches from 2010 to 2016 and a small decrease in the last year (2017-2018). Recruitment and Spawning stock biomass show a similar trend with increases in the last over several years (2010-2018), and $F$ varying along the series and showing a decrease in the last two years.

Figure 5.6.1 Red mullet in GSA 7. Stock summary of the assessment results. SSB and catch in tonnes, recruitment in number of individuals (thousand).

## Stock and exploitation status

The $F$ current computed as the geometric mean of the last three years of the time series ( $F_{\text {bar } 0-2 \text { ) }}$ is larger than $\mathrm{F}_{0.1}$. This indicates that Red mullet in GSA 7 is over exploited.

Table 5.6.1 Red mullet in GSA 7: State of the stock and fishery relative to reference points.

| Status | 2016 | 2017 | 2018 |
| :--- | :--- | :--- | :--- |

## Basis of the advice

Table 5.6.4 Red mullet in GSA 7: The basis of the advice.

| Advice basis | FMSY |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

This is an update of the EWG18-12 a4a assessment of red mullet in GSA 7, However a new Fbar range (1-2) was used in the analysis.
Current assessment results and survey indices have a similar trend. Residuals don't show anomalous values. Retrospective analyses are variable due to short time series, but consistently show $\mathrm{F}>$ Fmsy in all years

Figure 5.6.2 Red mullet in GSA 7. Retrospective analysis plots up 3 years back for recruitment, SSB, Catch and F.

## Issues relevant for the advice

No particular issues

## Reference points

### 5.7 Summary sheet for Norway lobster in GSA 5

## STECF advice on fishing opportunities

Based on precautionary considerations, STECF EWG 19-10 advises to decrease the total catch to $98 \%$ of the average 2016-2018 catches equivalent to catches of no more than 44.1 tons in each of 2020 and 2021 implemented either through catch restrictions or effort reduction for the relevant fleets.

## Stock development over time

Landings (Figure 5.7.1) have fluctuated over years but show recent rises, but without any evidence of increased effort. Only recent survey data since 2007 is considered useful due to the very small number of hauls prior to that year. The survey indicated that abundance has fluctuated in recent years unrelated to catch or catch per unit effort.

Figure 5.7.1 Norway lobster in GSA 5: Landing (t) from 2002 to 2018. MEDITS estimated biomass in the last ten years (blue) and recent changes (red) showing mean of last
two years (2017-2018) and previous three years (2014-2016) used for calculating catch advice.

## Stock and exploitation status

The status of the stock in terms of SSB and exploitation rate F is unknown.

## Catch scenarios

The advice on fishing opportunities for 2019 and 2020 is based on the recent observed catch adjusted to the change in the stock size index (MEDITS) for the two most recent values relative to the three preceding values (table 5.9.1). The precautionary buffer of $-20 \%$ is applied because the precautionary status of the stock is not known.

Table 5.7.1 Norway lobster in GSA 5: Assumptions made for the interim year and in the forecast. *

| Index A (2017-2018) |  | 2.70 |
| :--- | :--- | ---: |

$* * *$ catch advice $\times$ ( 1 - discard rate)
^ Advice value 2020 relative to advice value 2018.

## Basis of the advice

Table 5.7.4 Norway lobster in GSA 5: The basis of the advice.

| Advice basis | Precautionary Approach |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

The time series of available data is short. Due to incoherence in the landings and survey cohorts, instability of retrospective analysis and patterns in the residuals the assessment (a4a) was considered not acceptable and insufficient for the advice. EWG 19-10 decided to apply a surveybased assessment following the approach adopted by ICES for category 3 stocks.

## Issues relevant for the advice

Precautionary advice provided as an age based assessment was not available to provide advice based on a MSY approach.

## STECF EWG 19-10

### 5.8 Summary sheet for Norway lobster in GSA 6

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.11 and corresponding catches in 2020 should be no more than 77 tons.

## Stock development over time

The Nephrops norvegicus in GSA 6 shows decreasing catch from 2011 to 2016, stable in 20172018 and a recent increasing trend in SSB since 2016. F decrease in the last 3 years.

Figure 5.8.1 Norway lobster in GSA 6: Trends in catch, recruitment, fishing mortality and SSB resulting from the a4a model.

## Stock and exploitation status

The current level of fishing mortality is above the reference point $\mathrm{F}_{0.1}$, used as proxy of $\mathrm{Fmsy}^{\text {m }}$ (=0.11). SSB is increasing and $F$ is at the lowest level for the time series.

## Basis of the advice

Table 5.8.4 Norway lobster in GSA 6: The basis of the advice.

| Advice basis | FMSY |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

Both catches and survey indices showed good internal consistency. The retrospective analysis run on the a4a model indicates quite moderate stability for the model but do not change estimation of stock status over the last three years. All the diagnostics were considered acceptable.

## STECF EWG 19-10

### 5.9 Summary sheet for European hake in GSA 9, 10 and 11

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.22 and corresponding catches in 2020 should be no more than 772 tons.

## Stock development over time

Catches and SSB of European hake show a decreasing trend in the whole time series. The assessment shows a decreasing trend in the number of recruits with the minimum value reached in 2017. Fbar (1-3) shows a fluctuating pattern with a quite stable trend in the time series.

Figure 5.9.1 European hake in GSAs 9, 10 and 11: Trends in catch, recruitment, fishing mortality resulting from the a4a model.

## Stock and exploitation status

The current level of fishing mortality is above the reference point $\mathrm{F}_{0.1}$, used as proxy of $\mathrm{F}_{\text {Msy }}(=0.22$ ).

Table 5.9.1 European hake in GSAs 9, 10 and 11: State of the stock and fishery relative to reference points.

Sources and references

STECF EWG 19-10

### 5.10 Summary sheet for deep-water rose shrimp in GSA 9, 10 and 11

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more 0.97, and corresponding catches in 2020 should be no more than 1301 tonnes.

## Stock development over time

## Recruitment

Recruitment (age 0) is characterised by an increasing trend with a peak in 2016 (3,672,862 thousands individuals) and a strong fall in the last two years.

## Spawning stock biomass (SSB)

The spawning stock biomass shows an increasing trend reaching the maximum value in 2018 (2336 tons).

## Catch

After the minimum value in 2009 ( 750 tons), the catches have shown a constant increase over the years, until reaching the maximum value in 2018, corresponding to 1476 tons.

## Fishing mortality (F)

The lowest value of fishing mortality (0.67) is observed at the beginning of the data series (2009). F consistently increases reaching the maximum value of 1.05 in 2014. In the following three years $F$ decreased and in 2018 was 0.92 , showing a slightly increase in respect to the previous year.

Figure 5.10.1 Deep-water rose shrimp in GSAs 9, 10 \& 11. Outputs of the a4a assessment.

## Stock and exploitation status

Current $F$ ( 0.88 ), estimated as the mean $F_{b a r 1-2}$ in the last three years of the time series (2018), is lower than $\mathrm{F}_{0.1}(0.97)$, which is a proxy of $\mathrm{F}_{\mathrm{MSY}}$ used as the exploitation reference point consistent with high long term yields. This indicates that Deep-water rose shrimp stock in GSAs 9, 10 and 11 is exploited sustainably.

Table 5.10.1 Deep-water rose shrimp in GSAs 9, $10 \& 11$. State of the stock and fishery relative to reference points.

| Status | 2016 | 2017 | 2018 |

| Advice basis | FMSY |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

The retrospective analysis run on the a4a model showed consistent results. All the diagnostics were considered acceptable.

Figure 5.10.2
Deep-water rose shrimp in GSAs 9, 10 \& 11 Results of the retrospective analysis (a4a).

The time series of landing data in biomass available in the database were different among the three GSAs: 2003-2018 for GSA09, 2002-2018 for GSA10 and 2009-2018 for GSA11 so the assessment could only be run with the shortest time series 2009 to 2018.

The biomass discarded and the related length frequency distributions of Deep-water rose shrimp in GSA09 are available for the period 2009-2018. In GSA10, the data on discard are available for 2006 and for the years 2009-2017. With regard to GSA11, there are no data on this fraction of the catch. Missing discard data were not reconstructed.

## Issues relevant for the advice

No additional relevant issues for the advice.

STECF EWG 19-10

### 5.11

 Summary sheet for red mullet in GSA 9
## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.58 and corresponding catches in 2020 should be no more than 512 tons.

## Stock development over time

Catches and SSB of Red mullet show that after an increase since 2012, the past two years show a reduction, more pronounced for SSB and less for catches, and a corresponding increase in F.

Figure 5.11.1 Red mullet in GSA 9: Trends in catch, recruitment, fishing mortality and SSB resulting from the a4a model.

## Stock and exploitation status

The current level of fishing mortality is above the reference point $\mathrm{F}_{0.1}$, used as proxy of $\mathrm{F}_{\mathrm{msy}}$ (=0.58) .

## Sources and references

STECF EWG 19-10

### 5.12 Summary sheet for red mullet in GSA 10

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.41 and corresponding catches in 2020 should be no more than 309 tons.

## Stock development over time

Catches and SSB of Red mullet show that after a gradual increase since 2011, the trend reached a peak with stable catch and SSB, and decreasing F. However, recent reduced recruitment suggests that there is potential for stock to decline.

Figure 5.12.1 Red mullet in GSA 10: Trends in catch, recruitment, fishing mortality and SSB resulting from the a4a model.

## Stock and exploitation status

The current level of fishing mortality is above the reference point $F_{0.1}$, used as proxy of $\mathrm{F}_{\mathrm{msy}}$ ( $=0.41$ ).

Table 5.12.1 Red mullet in GSA 10: State of the stock and fishery relative to reference points.

## Basis of the advice

Table 5.12.4 Red mullet in GSA 10: The basis of the advice.

| Advice basis | $\mathrm{F}_{\mathrm{MSY}}$ |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

Both catches and survey indices showed good internal consistency. The retrospective analysis run on the a4a model showed consistent results with exception of recruitment which is poorly estimated in the last year. All the diagnostics were considered acceptable. There is uncertainty in allocation of length to age which leads to some instability in the assessment relative to last year.

Figure 5.12.2 Red mullet in GSA 10: Historical assessment results (final-year recruitment estimates included). (Retrospective graph)

## Issues relevant for the advice

No additional relevant issues for the advice.

## Reference points

STECF EWG 19-10

### 5.13 Summary sheet for Norway lobster in GSA 9

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.20 and corresponding to catches of no more than 142 tons in 2020 implemented either through catch restrictions or effort reduction for the relevant fleets.

## Stock development over time

Catches of Norway lobster in GSA 9 show a fluctuating pattern, with a peak in 1996-1997 After 2000 a decreasing trend is seen, with an increase in the last two years.
Recruitment (age 1) was higher in the first part of the time series. It remained at low values from 2002 to 2012, and then showed a slight increase, followed by a decrease.
SSB show a slight decreasing pattern until 2008, then is increasing in the last period of the time series.
Fishing mortality shows a fluctuating pattern, following the trend in the catches. $F$ is low in the last period (below the reference point), then increasing again in the last two years.

Figure 5.13.1 Norway lobster in GSA 9: Outputs of the assessment.

## Stock and exploitation status

The current level of fishing mortality is above the reference point $F_{0.1}$, used as proxy of $F_{\text {msy }}(=0.20)$. However, F was below the reference point in 2016 and at $F_{m s y}$ in 2017.

| Status | 2016 | 2017 | 2018 |
| :---: | :---: | :---: | :---: |
| $F / F_{\text {MSY }}$ | $F<F_{\text {MSY }}$ | $F$ at $F_{M S Y}$ | $F>F_{M S Y}$ |

| Advice basis | $\mathrm{F}_{\text {MSY }}$ |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

Landings from 1994 to 2002 were gathered from the Italian official statistics as collected by the RECFISH project (Ligas, 2019) the addition of this information has improved the assessment. Catches showed very good internal consistency, while the MEDITS survey showed poor internal consistency. The retrospective analysis run on the a4a model showed consistent results in terms of stock status. All the diagnostics were considered acceptable.
Reported landings in 2017 were considered unreliable, as very high. Despite the fact that official data were not revised, the national experts provided a new estimation of landings to STECF 1910 which was used.

### 5.14 Summary sheet for Norway lobster in GSA 11

## STECF advice on fishing opportunities

Based on precautionary considerations, STECF EWG 18-12 advises to decrease the total catch to $77 \%$ of the average 2015-2017 catches equivalent to catches of no more than 17.1 tons in each of 2019 and 2020 implemented either through catch restrictions or effort reduction for the relevant fleets.

## Stock development over time

In the period 1994 - 2010 MEDITS indices (Figure $5.14 .1 \mathrm{a}-\mathrm{b}$ ) show highly fluctuating pattern, ranging between 1.5 and 4.5 in terms of biomass $\left(\mathrm{kg} / \mathrm{Km}^{2}\right)$ and 31.1 and 129 in terms of density $\left(\mathrm{n} / \mathrm{Km}^{2}\right)$. On the contrary, during the latest 7 years density and biomass values show a more stable behaviour, oscillating respectively in the range 1.8-2.7 (average value 2.1) in terms of biomass and 37.7 - 58.6 (average value 47.3) in terms of density. Biomass and density average values along the whole time series were respectively $2.75 \mathrm{~kg} / \mathrm{Km}^{2}$ and $67.18 \mathrm{n} / \mathrm{Km}^{2}$.
The annual landings (Figure 5.14 .1 c) does not show a clear temporal pattern; the minimum value ( 6.3 tons) is recorded in the first year of the time series while an abrupt increase in landings is observed in 2006 ( 42.3 tons). Landing values in the period 2006-2012 ranged between 30 and 50 tons except in 2010 when landing falls below 25 tons. Finally, in the period 2013-2016 landings values are quite low, ranging between 15.8 and 20.6 while in the last year an increase in landings (28.3) is recorded.
LPUE values (Figure 5.14 .1 d) when compared to the MEDITS biomass (slope) show a good agreement in terms of temporal pattern except in 2011 and 2017 the last year of the time series.

Figure 5.14.1 Norway lobster in GSA 11: MEDITS indices (total biomass a; total density b), landings (c), number of vessels (c) and MEDITS biomass (slope) vs Landings Per Unit Effort (d)

## Stock and exploitation status

The stock status both in terms of SSB and exploitation rate (F) is unknown

## Catch scenarios

The advice on fishing opportunities for 2019 and 2020 is based on the recent observed catch adjusted to the change in the stock size index (MEDITS) for the two most recent values relative to the three preceding values (see table 5.14.1). The precautionary buffer of $-20 \%$ is applied because the precautionary status of the stock is not known.

Table 5.14.1 Norway lobster in GSA 11: Assumptions made for the interim year and in the forecast. *

| Index A (2016-2017) |  | 2.02 |
| :--- | :--- | :--- |
| Index B (2013-2015) |  | 2.09 |
| Index ratio (A/B) |  | 0.97 |
| $-20 \%$ Uncertainty cap | Applied/not applied | Not applied |
| Average catch (2015-2017) |  | 22.1 |
| Discard rate (2015-2017) |  | Applied/not applied |

* The figures in the table are rounded. Calculations were done with unrounded inputs and computed values may not match exactly when calculated using the rounded figures in the table.

$\wedge$ Advice value 2019 relative to advice value 2018.

## Basis of the advice

Table 5.14.2 Norway lobster in GSA 11: The basis of the advice.

| Advice basis | Precautionary Approach |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

XSA and a4a results were considered as not acceptable due to incoherence in the landings cohorts and patterns in the residuals. $F$ values estimated by XSA and a4a were also different. EWG 18-12 decided to apply a survey-based assessment following the approach adopted by ICES for category 3 stocks.

## Issues relevant for the advice

Precautionary advice provided as an age based assessment was not available to provide advice based on a MSY approach.

### 5.15 Summary sheet for blue and red shrimp in GSA 1

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.56 and corresponding catches of blue and red shrimp in 2020 should not exceed 96 tonnes.

## Stock development over time

The Spawing stock biomass (SSB) shows a clear decreasing trend since 2012 but appear rather stable in the last three years. Recruitment shows similar declining pattern since 2005 (highest value in the time series). The recruitment in 2018 was 250,000 individuals, near the mean of the time series. Catches have declined from around 250 t in 2002-2004 to around 100 t in 2018, with a clear declining trend since 2014. Fishing mortality $(F)$ has been exceeding F0.1 since 2003. It declined in the early part of the time-series but has fluctuated around 1.0 until 2017 but has increased again in the last year to 1.14 .

Figure 5.15.1. Blue and red shrimp in GSA 1. Stock summary of the assessment (a4a) results. SSB and catch are in tonnes, recruitment in number of individuals.

## Stock and exploitation status

The current $\mathrm{F}(=1.15)$ computed as the mean of the last three years, 2015-2017) was larger than $F_{0.1}(0.56)$, which is a proxy of $F_{M S Y}$ and is used as the exploitation reference point consistent with high long term yields. This indicates that blue and red shrimp in GSA 1 is over exploited.

Table 5.15.1 Blue and red shrimp in GSA 1. State of the stock and fishery relative to reference points.

| Status | 2016 | 2017 | 2018 |

## Basis of the advice

Table 5.15.4 Blue and red shrimp in GSA 1. The basis of the advice.

| Advice basis | MSY approach. |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

The recruitment and SSB estimates shown for the last years are uncertain due to variation in MEDITS index. The retrospective performance is considered adequate as this does not change the status of the stock ( $\mathrm{F}>$ Fmsy for recent period), however due to short time series more years of restrspective could not be run indicating some instability in the assessment.

Figure 5.15.2 Blue and red shrimp in GSA 1. Results of the retrospective analysis (a4a).
Data treatment was revised in 2019, to deal with potential miss age allocation. This results in fewer age 0 in catch and survey. The Fbar is revised and rescaled, although the value of Fbar and Fmsy are revised the ratio is unaltered.

## Issues relevant for the advice

There are no additional issues for the advice.e

## Reference points

## Basis of the assessment

The stock of blue and red shrimp in GSA 1 was assessed using the statistical catch-at-age method (a4a) that were applied to catch data for the period 2002-2018, tuned with fishery independent survey abundance indices (MEDITS in GSA 1).

The the natural mortality of blue and red shrimp in the present assessment was calculated as a vector using the Chen Watanabe (1989) model.

Table 5.15.6 Blue and red shrimp in GSA 1. Basis of the assessment and advice.

| Assessment type | Statistical catch-at-age method (a4a) |
| :--- | :--- |
| Input data | Commercial catches (2002-2017) from one fleet (OTB) and one tuning index, <br> MEDITS bottom trawl survey (CPUE, kg/km², 2002-2017). Percentage maturity from <br> previous assessment, natural mortality estimated as a vector. |

## Sources and references

### 5.16 Summary sheet for blue and red shrimp in GSA 5

## STECF advice on fishing opportunities

Based on precautionary considerations, STECF EWG 18-12 advises to decrease the total catch to $88 \%$ of the average 2015-2017 catches equivalent to catches of no more than 150 tons in each of 2019 and 2020 implemented either through catch restrictions or effort reduction for the relevant fleets.

## Stock development over time

The relative change in the estimated $S S B$ was used to provide an index for change (Figure 5.16.1).

Figure 5.16.1 Blue and red shrimp in GSA5. A) Summary of the MEDITS stock indicator showing mean value 2013 to $2015=2.44$, mean 2016-2017 $=4.67$ and b) Landings by year.

## Stock and exploitation status

The stock status both in terms of SSB and exploitation rate (F) is unknown.

## Catch scenarios

The advice on fishing opportunities for 2019 and 2020 is based on the recent observed catch adjusted to the change in the stock size index. The change is estimated from the two most recent values relative to the three preceding values (see table 5.16.1). The precautionary buffer of $-20 \%$ is applied because the precautionary status of the stock is not known.

Table 5.16.2 Blue and red shrimp in GSA 5. Assumptions made for the interim year and in the forecast. *

| Index A (2016-2017) |  |  | 4.27 |
| :---: | :---: | :---: | :---: |
| Index B (2013-2015) |  |  | 2.44 |
| Index ratio (A/B) |  |  | 1.75 |
| -20\% Uncertainty cap | Applied/not applied | Applied |  |
| Average catch (2015-2017) |  |  | 156.5 |
| Discard rate (2015-2017) |  | Assumed negligible | 0 |

| $-20 \%$ Precautionary buffer | Applied/not applied | Applied |

## Basis of the advice

Table 5.16.3 Blue and red shrimp in GSA 5. The basis of the advice.

| Advice basis | Precautionary Approach |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

Both models showed oscillations along the data series, both for recruitment and SSB. However, a4a showed an increase of both parameters for the last years. F values were higher for a4a than for XSA, but this was considered as the most unstable parameter. The assessments were not accepted for advice. Biomass and abundance indices from the MEDITS survey showed oscillations along the years, without a clear trend, but appear to be acceptable for index advice

### 5.17 Summary sheet for blue and red shrimp in GSAs 6 \& 7

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.33 and corresponding catches of blue and red shrimp in 2020 should not exceed 226 tonnes.

## Stock development over time

The SSB shows some increase after 2015, but decreased again after 2017. Catch is estimated to be decreasing consistently from 2011 onwards. Fishing mortality is seen to slightly increase after 2015.

Figure 5.17.1 Blue and red shrimp (ARA) in GSAs 6 \& 7. Outputs of the a4a assessment. SSB and catch are in tonnes, recruitment in number of individuals.

## Stock and exploitation status

The current $F(=1.26)$ computed as the mean of the last three years, 2015-2017) was larger than $\mathrm{F}_{0.1}$ ( 0.33 ), which is a proxy of $\mathrm{F}_{\text {MSy }}$ and is used as the exploitation reference point consistent with high long term yields. This indicates that blue and red shrimp in GSA 6 and 7 is over exploited.

Table 5.17.1 Blue and red shrimp in GSA 6 \& 7. State of the stock and fishery relative to reference points.

## Quality of the assessment

Two assessments were run with input data from two alternative approaches of slicing LFD data, (the two assessments are presented in Ch. 6.17). The assessment with input data acounting for summer spawning of the stock was prefered and is presented in the stock summary, the results of the assessment give slightly higher F and similar MSY reference point. The conclusions that F> FMSY is robust to all options $^{\text {m }}$

Figure 5.17.2 Blue and red shrimp in GSAs 6 \& 7: Historical assessment results (final-year recruitment estimates included). (Retrospective graph)

No VBGF parameters per sex were available, combined growth parameters were used despite assessing a species showing sex dimorphism. The same holds for LW relationship parameters and maturity at length.

## Issues relevant for the advice

No additional relevant issues for the advice.

## Sources and references

### 5.18 Summary sheet for blue and red shrimp in GSA 9, 10 \& 11

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2019 should be no more than 0.39 and corresponding catches in 2020 should be no more than 72 tons.

## Stock development over time

SSB of Blue and red shrimp show a fluctuating pattern reaching the lowest value in 2018 (353 tonnes). Recruitment fluctuates similarly also with a minimum in 2018 (21035). Fbar (2-5) shows a fluctuating pattern with a steep increase in the last years (Fbar $2018=1.45$ ).

Figure 5.18.1 Blue and red shrimp in GSAs 9, 10 and 11: Trends in catch, recruitment, fishing mortality resulting from the a4a model.

## Stock and exploitation status

The current level of fishing mortality is above the reference point $\mathrm{F}_{0.1}$, used as proxy of $\mathrm{F}_{\mathrm{MSY}}(=0.39)$.

Table 5.18.1 Blue and red shrimp in GSAs 9, 10 and 11: State of the stock and fishery relative to reference points.

## Sources and references

STECF EWG 19-10

### 5.19 Summary sheet for giant red shrimp in GSA 9, 10 \& 11

## STECF advice on fishing opportunities

STECF EWG 19-10 advises that when MSY considerations are applied the fishing mortality in 2020 should be no more than 0.44 and corresponding to catches of no more than 199 tons in 2020 implemented either through catch restrictions or effort reduction for the relevant fleets.

## Stock development over time

Catches of giant red shrimp in GSAs 9, 10, 11 shows a fluctuating pattern, with peaks in 2006 and 2014, then increasing again in the last two years. Recruitment and SSB peaked in 2011 and 2013, respectively; after that, they showed a decreasing trend. Fishing mortality showed a rather constant pattern between 0.5 and 0.8 , with a sharp increase in the last two years due to the increase in catches.

Catches of giant red shrimp in GSAs 9, 10, 11 shows a fluctuating pattern, with peaks in 2006 and 2014, then increasing again in the last two years. Recruitment and SSB peaked in 2011 and 2013, respectively; after that, they showed a decreasing trend. Fishing mortality showed a rather constant pattern between 0.5 and 0.8 , with a sharp increase in the last two year due to the increase in catches.

Figure 5.18.1 Giant red shrimp in GSAs 9, 10, 11: Output of the assessment.

## Stock and exploitation status

The current level of fishing mortality is well above the reference point $F_{0.1}$, used as proxy of $\mathrm{F}_{\text {msy }}(=0.45)$. However, F has been very close to or at $\mathrm{F}_{\text {MSY }}$ in 2016 and previous years.

| Status | 2016 | 2017 | 2018 |
| :---: | :---: | :---: | :---: |
| $F / F_{\text {MSY }}$ | $F$ at $F_{\text {MSY }}$ | $F>F_{M S Y}$ | $F>F_{M S Y}$ |

## Basis of the advice

Table 5.19.4 Giant red shrimp in GSAs 9, 10, 11 The basis of the advice.

| Advice basis | $\mathrm{F}_{\text {MSY }}$ |
| :--- | :--- |
| Management plan |  |

## Quality of the assessment

Catches showed good internal consistency, which is slightly lower in the survey indices. The retrospective analysis run on the a4a model showed moderately consistent results with some evidence of overestimation of SSB and underestimation of $F$, but in all cases the conclusion of $F$ relative to $\mathrm{F}_{\mathrm{MSY}}$ is maintained. All the diagnostics were considered acceptable.

Figure 5.19.2 Giant red shrimp in GSA 9, 10, 11: Historical assessment results (final-year recruitment estimates included). (Retrospective graph)

At STECF 18-12, no sex ratio (and maturity vector) at length was available for GSA 11, thus the vectors available for GSA 10 were used to split the LFDs of GSA 11 in LFDs by sex. This information was made available to STECF 19-10, and then used to prepare the stock object.
Information on landings for quarter III in 2017 and quarter I in 2018 for GSA 10 was missing. The information was requested to the Italian National Correspondent and made available to the EWG in due time. In GSA 11, landings data for OTB_DWS were missing from 2015 to 2018. Landings data were recovered from the FDI data; this required rerunning the assessment after the EWG.
MEDITS contained some missing values ("pfrac" and "pechan" (TC) of hauls 29 and 67 of GSA10 in 2017) these were corrected but resubmission is required.

## Issues relevant for the advice

No additional relevant issues for the advice.

## Reference points

Sources and references

## 6 Stock Assessments

ToR 1. To compile and provide the most updated information on stock identification and boundaries, length and age composition, growth, maturity, feeding, essential fish habitats and natural mortality.

ToR 2. To compile and provide complete sets of annual data on landings and discards for the longest time series available up to and including 2018, including length frequency distribution over time.

ToR 3. To compile and provide complete sets of annual data on fishing effort for the longest time series available up to and including 2018. This should be described in terms of fishing days, days at sea, GT*days and nominal effort by Member State, GSA and fishing gear.

ToR 4. To compile and provide indices of abundances and biomass by year and size/age structure for the longest time series available up to and including 2018. Where possible, the EWG should take into account the results of the EU-funded project RECFISH

ToR 5. To assess trends in historic and recent stock parameters on fishing mortality, stock biomass, spawning stock biomass, and recruitment. Different assessment models should be applied as appropriate, including retrospective analyses. The selection of the most reliable assessment shall be explained. Assumptions and uncertainties shall be specified. To assist with development of management plans, give preference to models that allow estimation of uncertainty, in line with the recommendations of STECF EWG 17-07.

ToR 6. To estimate the $F_{M S Y}$ point value, range of $F_{M S Y}$ (i.e. MSY $F_{\text {LOWER }}$ and MSY $F_{U P P E R}$ ) and the conservation reference points (i.e. $B_{P A}$ and $B_{L I M}$ ), or proxy. The proposed values shall be related to long-term high yields and low risk of stock/fishery collapse and ensure that the exploitation levels restore and maintain marine biological resources at least at levels which can produce the maximum sustainable yield.

ToR 7. To provide short and medium term forecasts of spawning stock biomass, stock biomass and catches. The forecasts shall include different management scenarios, including: the status quo fishing mortality and target $F_{\text {MSY }}$ range (i.e. $F_{\text {MSY }}$ point value, MSY $F_{\text {LOWER }}$ and MSY $F_{\text {UPPER }}$ ) or other appropriate proxy by 2020 and 2025.

### 6.1 HAKE IN GSA 1, 5, 6 \&7

### 6.1.1 Stock Identity and Biology

The assessment of European hake carried out during the STECF EWG 19-10 considered the stock shared by GSAs 1, 5, 6 and 7 .

Figure 6.1.1.1 Geographical location of GSAs 1, 5, 6 and 7.
A sex combined model was applied to this stock, as information by sex was not available for the GSAs considered. All the parameters used were the same as in the previous assessment for hake in this area, carried out during the STECF EWG 18-12.

The growth parameters used were those estimated by Mellon-Duval et al. (2010) from tagging experiments in the Gulf of Lions; length-weight relationship parameters were those estimated in the Spanish Data Collection Framework (Tab. 6.1.1.1 and Fig. 6.1.1.2).

Table 6.1.1.1 European hake in GSAs 1, 5, 6 and 7. Growth parameters and length-weight relationship parameters.

| $L_{\text {inf }}$ | $k$ | t0 | $a$ | $b$ |
| :---: | :---: | :---: | :---: | :---: |
| 110 | 0.178 | 0 | 0.00677 | 3.0351 |

Figure 6.1.1.2. European hake in GSAs 1, 5, 6 and 7. Von Bertalanffy growth curve.

The maturity vector was taken from García-Rodríguez and Esteban (1995); the natural mortality vector was estimated using PRODBIOM (Abella et al, 1997) (Tab. 6.1.1.2).

Table 6.1.1.2. European hake in GSAs 1, 5, 6 and 7. Maturity and natural mortality vectors used in the assessment.

| Age | Maturity | M |
| :---: | :---: | :---: |
| 0 | 0 | 1.24 |
| 1 | 0.15 | 0.58 |
| 2 | 0.82 | 0.45 |
| 3 | 0.98 | 0.4 |
| 4 | 1 | 0.37 |
| $5+$ | 1 | 0.35 |

### 6.1.2 DATA

### 6.1.2.1 CATCH (LANDINGS AND DISCARDS)

European hake is largely exploited in GSAs 1 and 6, mainly by trawlers on the shelf and slope, but also by small-scale fisheries using long lines, gill nets and trammel nets. In GSA 5, hake catches come exclusively from bottom trawlers. They show important variation along the data series, between 50 and 200 tons. In the Gulf of Lions (GSA 7), hake is exploited by French trawlers, French gillnetters, Spanish trawlers and Spanish longliners.

## Landings

Landings data were reported to STECF EWG 18-12 through the DCF. In GSAs $1,5,6$ and 7 , most of the landings come from otter trawls. The contribution of set nets and longlines to the total landing is around the $4 \%$ each. Landings data by year, GSA, country and fleet are presented in Figure 6.1.2.1.1, total landings by year are presented in Table 6.1.2.1.1.

HKE_ESP_5_TOTAL_LANDING

Figure 6.1.2.1.1. European hake in GSAs 1,5, 6 and 7. Landings data in tons by year GSA country and fleet (for France in GSA 7 landings data are shown by year and gear for visualization reasons). From 2015 onwards there can be two points in the same year due to the increase in "fishery classes" for the same gear. Showing all the fishery classes and gears was overly complex, so the fishery classes for the same gear are both sown. As each fishery has different values it is possible to get double points or trends.

Table 6.1.2.1.1. European hake in GSAs 1, 5, 6 and 7. Total landings data in tons by year.

|  | Total Landing (tons) |
| :---: | :---: |
| $\mathbf{2 0 0 2}$ | 6138 |
| $\mathbf{2 0 0 3}$ | 7666 |
| $\mathbf{2 0 0 4}$ | 5039 |
| $\mathbf{2 0 0 5}$ | 5156 |
| $\mathbf{2 0 0 6}$ | 5558 |
| $\mathbf{2 0 0 7}$ | 4697 |
| $\mathbf{2 0 0 8}$ | 6082 |
| $\mathbf{2 0 0 9}$ | 7362 |
| $\mathbf{2 0 1 0}$ | 5466 |
| $\mathbf{2 0 1 1}$ | 5279 |
| $\mathbf{2 0 1 2}$ | 4278 |
| $\mathbf{2 0 1 3}$ | 5131 |
| $\mathbf{2 0 1 4}$ | 4786 |
| $\mathbf{2 0 1 5}$ | 3129 |
| $\mathbf{2 0 1 6}$ | 3083 |
| $\mathbf{2 0 1 7}$ | 2946 |
| $\mathbf{2 0 1 8}$ | 3831 |

Length frequency distribution of the landings by year and gear or fleet from the DCF database is presented in Figure 6.1.2.1.2. When data are reported by gear different fisheries within gears are represented by different colours (to reduce number of rows).

Figure 6.1.2.1.2. European hake in GSAs 1, 5, 6 and 7. Length frequency distribution of the landings by year and gear or fleet.

## Discards

Discards data were reported to STECF EWG 19-10 through the DCF, and they were included in the stock assessment. For the years in which discards data were missing, they were estimated on the basis of the discard ratio (discard/landing) of the available years and the landing time series.

The highest discard rates were represented by the bottom trawl fishery; for the other gears the discards were negligible. Total discard by year for the bottom trawl fishery is presented in Table 6.1.2.1.2.

Table 6.1.2.1.2. European hake in GSAs $1,5,6$ and 7 . OTB discards data in tons by GSA.

|  | $\mathbf{2 0 0 5}$ | $\mathbf{2 0 0 6}$ | $\mathbf{2 0 0 7}$ | $\mathbf{2 0 0 8}$ | $\mathbf{2 0 0 9}$ | $\mathbf{2 0 1 0}$ | $\mathbf{2 0 1 1}$ | $\mathbf{2 0 1 2}$ | $\mathbf{2 0 1 3}$ | $\mathbf{2 0 1 4}$ | $\mathbf{2 0 1 5}$ | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 7}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{2 0 1 8}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |
| GSA 1 | 19.3 | 24.2 | 19.1 | 13.2 | 20.8 | 14.9 | 5.8 | 20.8 | 10.4 | 30.5 | 23.5 | 24.9 | 21.4 |
| GSA 5 | 12.2 | 11.9 | 9.4 | 7.1 | 16.2 | 19.2 | 6.5 | 6.5 | 13.1 | 5.6 | 0.6 | 9.8 | 4.1 |

### 6.1.2.3 SURVEY DATA

The MEDITS (Mediterranean International Trawl Survey) survey is an extensive trawl survey occurring in all European countries and included in the Data Collection Framework. According to the MEDITS protocol (Bertrand et al., 2002), it takes places every year during springtime, following a random stratified sampling by depth ( 5 strata: 0-50 m,50-100 m, 100-200 m, 200500 m and over 500 m ). The number of hauls in each stratum is proportional to the surface of the
stratum and their positions were randomly selected and maintained fixed throughout the time. Same sampling gear (GOC73), characterized by a 20 mm stretched mesh size cod-end, and is used throughout GSAs and years.

Since 1994, the MEDITS surveys have been regularly carried out each year during the spring season. In the current assessment combined MEDITS data for GSAs 1-5-6-7 from 2007 onwards were used, as in GSA 5 the survey has been carried out consistently only from that year. The Balearic Islands, in fact, were partially covered by the MEDITS survey during 1994-2006, with a very low number of hauls by year, covering only a small part of the area (Ibiza channel). Thus, only the information collected from 2007, when the sampling was extended, was considered reliable for the analysis.

The combined MEDITS indexes were calculated using the script provided by JRC (Figures 6.1.2.3.1 and 6.1.2.3.2).

Figure 6.1.2.3.1. European hake in GSAs 1, 5, 6 and 7. Estimated biomass indices from the MEDITS survey (kg/km²).

Figure 6.1.2.3.2. European hake in GSAs 1, 5, 6 and 7. Estimated density indices from the MEDITS survey ( $\mathrm{n} / \mathrm{km}^{2}$ ).

Both estimated abundance and biomass indices show similar trends, with strong fluctuations throughout the time series and a slight increase in the last year.

Size structure indices are shown in Figure 6.1.2.3.3.

Figure 6.1.2.3.3. European hake in GSAs 1, 5, 6 and 7. Length frequency distribution by year of MEDITS survey.

### 6.1.3 STOCK ASSESSMENT

A statistical catch-at-age assessment was carried out for this stock, using the Assessment for All Initiative (a4a) method (Jardim et al., 2015). The a4a method utilizes catch-at-age data to derive estimates of historical population size and fishing mortality. However, unlike XSA, model parameters estimated using catch-at-age analysis are done so by propagation of population forward in time and analyses do not require the assumption that removals from the fishery are known without error.

The assessment was carried out using the period 2007-2018 for catch data and tuning file, as survey indices data were available only from 2007 for GSA 5. Both catch numbers at length and index number at length were sliced using the a4a age slicing routine in FLR. The analyses were carried out for the ages 0 to $5+$. Concerning the Fbar, the age range used was 1-3 age classes.

## Input data

The growth parameters used for VBGF were the one reported in table 6.1.1.1.
Total catches and catch numbers at age from the single GSAs were used as input data. SOP correction was applied to catch numbers at age (Table 6.1.3.1).

Table 6.1.3.1. European hake in GSAs 1,5, 6 and 7. SOP correction vector.

## Assessment results

Different a4a models were performed (combination of different $f, q$ and $s r$ ). The best model (according to residuals and retrospective) included: $f \sim s($ age, $k=4)+s(y e a r, k=6)+s(y e a r$, $\mathrm{k}=6$, by $=$ as.numeric $(\mathrm{age}==0))+\mathrm{s}($ year, $\mathrm{k}=6$, by=as.numeric $($ age $==4)$ )
$\mathrm{q} \sim \mathrm{I}(1 /(1+\exp (-$ age $)))$

The use of additional parameters on age 0 an age 4 in the fishery model were included to allow the model to fit better to the first few years of the data which show higher catches particularly at age 0 . These extra terms also improved the retrospective performance, suggesting the early years are indeed different from the recent year's fishery.

Results are shown in Figures 6.1.3.3-6.1.3.9

Figure 6.1.3.3. European hake in GSAs 1, 5, 6 and 7 . Stock summary from the final a4a model.

## Retrospective

The retrospective analysis was applied up only to 3 years back, due to the short time series. Models results were quite stable (Figure 6.1.3.8) except for recruitment which is estimated poorly in the terminal year of the assessment.

Figure 6.1.3.8. European hake in GSAs 1, 5, 6 and 7. Retrospective analysis.

Figure 6.1.3.9. European hake in GSAs 1, 5, 6 and 7. Simulations

In the following tables, the population estimates obtained by the a4a model are provided.

Based on the a4a results, the European hake SSB shows a decreasing trend from 2009 to 2016 (from 4618 to 1546 tons), with a slight increase in the last two years (1728 tons in 2018). The assessment shows a decreasing trend in the number of recruits in the time series. The recruitment (age 0) reached a minimum of 115253 thousands individuals in 2014, there has been an increase up to 2017 ( 178090 thousands). Fbar (1-3) shows a slight upward trend in the time series since 2010 increasing from a value of 1.71 to a value of 1.87 in 2018. A maximum peak of 1.90 was reached in 2014.

### 6.1.4 Reference Points

The time series is too short to fit a stock recruitment relationship, reference points are based on equilibrium methods. The STECF EWG 18-02 recommended using $\mathrm{F}_{0.1}$ as a proxy of $\mathrm{F}_{\text {msy. }}$. The library FLBRP available in FLR was used to estimate $\mathrm{F}_{0.1}$ from the stock object resulting from the outputs of the a4a assessment.

Current F (1.84, estimated as the average of the $\mathrm{F}_{\mathrm{bar1} 1-3}$ in the last three years of the time series) is much higher than $\mathrm{F}_{0.1}(0.38)$, chosen as a proxy for $\mathrm{F}_{\text {MSY }}$ and as the exploitation reference point consistent with high long-term yields. This indicates that European hake stock in GSAs 1, 5, 6 and 7 is highly over-exploited.

### 6.1.5 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the a4a stock assessment.

An average of the last three years was used for weight at age and maturity at age, while the $F_{\text {bar }}$ $=1.84$ (average of the last three years' $F$ from the $a 4 a$ assessment) was used for $F$ in 2019, as $F$ is rising (See section 4.3). Recruitment is observed to decline over the period of the assessment (Figure 6.1.3.9), but becomes stable from 2010, so the last 9 years are used as an estimate of recruits in 2019 to 2020. Recruitment (age 0) was estimated from the population results as the geometric mean of the last 9 years (150432).

Table 6.1.5.1 European hake in GSAs 1, 5, 6 and 7: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :---: | :---: | :---: |

### 6.1.6 Data Deficiencies

The same data deficiencies encountered in EWG 18-12 were found in last year (2018) data and within the whole time series.
French data
In some years and for some hauls, hake MEDITS data seem biased due to have applied a very high raising factor. This fact could occur in TB data too.

## Spanish data

In some years and for some hauls, hake MEDITS data seem biased due to have applied a very high raising factor. This fact could occur in TB data too.

### 6.2 DEEP-WATER ROSE SHRIMP IN GSA 1, 5, 6 \& 7

### 6.2.1 Stock Identity and Biology

Figure 6.2.1.1. Geographical location of GSAs 1-5-6-7.

An advice on DPS in GSAs 1-5-6-7 based on SSB and MEDITS trends was already given in 2018 for 2020 and can be taken directly from STECF EWG 18-12 report. STECF EWG 19-10 was asked to perform a short evaluation of survey data to determine if new data (2019) is different and could help with an assessment.
Growth parameters and length-weight relationship parameters were estimated within the DCF 2019 for sexes combined and carapace length expressed in mm.

Table 6.2.1.1. Deep-water rose shrimp GSAs $1-5-6-7$. Growth parameters and length-weight relationship parameters.

| Country | Area | Year | $\mathbf{L}_{\boldsymbol{\infty}}$ | $\mathbf{K}$ | $\mathbf{t}_{\mathbf{0}}$ | $\mathbf{a}$ | $\mathbf{b}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ESP | GSA 1 | 2018 | 47 | 0.689 | -0.12 | 0.004 | 2.347 |
| ESP | GSA 5 | 2018 | 47 | 0.76 | 0 | 0.002 | 2.567 |
| ESP | GSA 6 | 2018 | 47 | 0.764 | 0 | 0.002 | 2.591 |

The von Bertalanffy did not change significantly from the previous single GSA assessments done during the previous STECF EWG.

The vector of proportion of mature individuals by age has been derived by slicing the maturity ogive by length with the von Bertalanffy coefficients.

A vector of natural mortality was estimated by PRODBIOM method (Abella et al., 1997) using growth and length-weight relationship parameters for sex combined for each GSA.

Table 6.2.1.2. Deep-water rose shrimp GSAs $1-5-6-7$. Proportion of mature specimens at age and natural mortality at age by GSA.

| Age | Area | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3 +}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Maturity | GSA 1-5-6-7 | 0 | 1 | 1 | 1 |
| $\mathbf{M}$ | GSA 1 | 1.52 | 0.84 | 0.7 | 0.65 |
| M | GSA 5 | 1.65 | 0.89 | 0.74 | 0.67 |
| $\mathbf{M}$ | GSA 6-7 | 1.62 | 0.88 | 0.73 | 0.67 |

### 6.2.2 DATA

### 6.2.2.1 CATCH (LANDINGS AND DISCARDS)

## General description of Fisheries

Deep-water rose shrimp is targeted mainly by bottom trawlers in these areas.
Deep-water rose shrimp is a target species for trawling vessels operating on the upper slope and it is one of the most important crustacean species for the trawl fisheries of GSA 01. No artisanal boats target this species.

In GSA 5 the deep-water rose shrimp is an important by-catch species in the upper slope.
In GSA 6 it is estimated that half of the trawl fleet operates on deep-water rose shrimp fishing grounds and other deep-water fishing grounds, targeting other valuable crustaceans (Norway lobster; red shrimp).

In GSA 7, Deep-water rose shrimp is exploited mainly by Spanish and French trawlers.

## Landings

Landings data were reported to STECF EWG 19-10 through the DCF. In GSAs 1, 5, 6 and 7, most of the landings come from otter trawls. DCF data coming from other gear were considered inaccurate or sampled inconsistently (Table 6.2.2.1.1).

Table 6.2.2.1.1. Deep-water rose shrimp GSAs 1-5-6-7. Landings data in tonnes by fleet.

Figure 6.2.2.1.1. Deep-water rose shrimp GSAs 1 and 5. Landings data in tonnes by year and fleet.

Figure 6.2.2.1.2. Deep-water rose shrimp GSAs 6 and 7 (Spain). Landings data in tonnes by year and fleet.

Figure 6.2.2.1.3. Deep-water rose shrimp GSA 7 (France). Landings data in tonnes by year and fleet.

Length frequency distribution of the landings by year and fleet from the DCF database are presented in Figures 6.2.2.1.4.-5.

In GSA 1, length frequency distributions were not available for 2002 and for all years of OTBMDDWSP.

In GSA 5, length frequency distributions were not available for 2016. For OTB-MDDWSP data were lacking for the years 2009 and 2018.

In GSA 6, length frequency distributions were not available for all years of OTB-MDDWSP. The length frequency distribution in 2015 had an error.

In GSA 7, only the length frequency distributions for Spanish OTB were available.

Figure 6.2.2.1.4. Deep-water rose shrimp GSAs 1 and 5. Length frequency distribution of the landings by year and fleet.

Figure 6.2.2.1.5. Deep-water rose shrimp GSAs 6 and 7 (Spain). Length frequency distribution of the landings by year and fleet.

## Discards

Discards data were reported to STECF EWG 19-10 through the DCF. Total discard by fleet and year are presented in table 6.2.2.1.3.

### 6.2.2.3 SURVEY DATA

Since 1994, MEDITS trawl surveys has been regularly carried out each year during the spring season. The MEDITS in GSA 5 has been carried out consistently only from 2007. The different GSAs MEDITS indexes were merged using an average weighted by the GSA area.

The sampling design of MEDITS is random stratified with number of haul by stratum proportional to stratum surface. Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Hauls noted as valid were used only, including stations with no catches (zero catches are included). Based on the DCF data call, abundance and biomass indices for combined GSAs were re-calculated.

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means. This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

Yst $=\Sigma\left(Y_{i}{ }^{*} A i\right) / A$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / A^{2}$
Where:
A=total survey area
$A i=$ area of the $i$-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a deltadistribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial. Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance*100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA.

Observed abundance and biomass indices of Deep-water rose shrimp and the length frequency distributions are given in the figures below both for single GSA and combined GSAs (Figures 6.2.2.3.1-10).

Both estimated abundance and biomass indices show similar trends in GSAs 5 and 6, with a sharp increase in the last years. In GSA 1 the trend is more variable throughout the time series; however, also in this area a high value is observed in 2018. In GSA 7, a sharp increase was observed in 2015 and 2016, while in 2018 both density and biomass showed a reduction in respect to the previous years.

Considering the whole area (GSAs 1-5-6-7) the density and biomass indices showed a sharp increase in the last three years (2016-2018), reaching the maximum values in the last year of the data series.

Figure 6.2.2.3.1. Deep-water rose shrimp GSA 1. Estimated density ( $\mathrm{N} / \mathrm{km}^{2}$ ) and biomass $\left(\mathrm{kg} / \mathrm{km}^{2}\right)$ indices.

Figure 6.2.2.3.2. Deep-water rose shrimp GSA 5. Estimated density ( $\mathrm{N} / \mathrm{km}^{2}$ ) and biomass ( $\mathrm{kg} / \mathrm{km}^{2}$ ) indices.

Figure 6.2.2.3.3. Deep-water rose shrimp GSA 6. Estimated density ( $\mathrm{N} / \mathrm{km}^{2}$ ) and biomass ( $\mathrm{kg} / \mathrm{km}^{2}$ ) indices.

Figure 6.2.2.3.4. Deep-water rose shrimp GSA 7. Estimated density ( $\mathrm{N} / \mathrm{km}^{2}$ ) and biomass $\left(\mathrm{kg} / \mathrm{km}^{2}\right)$ indices.

Figure 6.2.2.3.5. Deep-water rose shrimp GSAs $1-5-6-7$. Estimated density ( $\mathrm{N} / \mathrm{km}^{2}$ ) and biomass ( $\mathrm{kg} / \mathrm{km}^{2}$ ) combined MEDITS indices.

Figure 6.2.2.3.6. Deep-water rose shrimp GSA 1. Length frequency distribution by year of MEDITS.

Figure 6.2.2.3.7. Deep-water rose shrimp GSA 5. Length frequency distribution by year of MEDITS.

Figure 6.2.2.3.8. Deep-water rose shrimp GSA 6. Length frequency distribution by year of MEDITS.

Figure 6.2.2.3.9. Deep-water rose shrimp GSA 7. Length frequency distribution by year of MEDITS.

Figure 6.2.2.3.10. Deep-water rose shrimp GSAs 1-5-6-7. Length frequency distribution by year of MEDITS.

The following maps show the abundance (in biomass) per haul of the MEDITS survey standardized to square kilometre. It is evident as in the first years the abundance of Deep-water rose shrimp was low in all the GSAs.

Since end of '90s, the abundance of the species increased in the southern part (GSA 1). In the following years, the species showed an expansion of the distribution area towards the north. In the last four years, the species resulted abundant in all the GSAs.

### 6.2.3 STOCK ASSESSMENT

The EWG 18-12 concluded that the outputs of the XSA and a4a model were not suitable to provide the basis of the current status of the stock but could be used as indicative of a trend. On this basis, advice was given for the years 2019 and 2020.
EWG 19-10 was required to do a short evaluation of survey and landing trends to determine if new data is different and could help with an assessment. As no substantive change in survey and landing signals was observed, a new assessment has not been performed and the advice done in EWG 18-12 has been confirmed.

### 6.2.4 Reference Points

As the assessment carried out during EWG 18-12 was not accepted for advice, reference points were not calculated.

### 6.2.5 Short term Forecast and Catch Options

No new short term forecast has been carried out as advice given last year is valid fpor 2020. Details of the 2018 assessment are avaiable in STECF EWG 18-12 report.

### 6.2.6 Data Deficiencies

Data from DCF 2018 as submitted through the Official data call in 2019 were used.
In GSA 1, no length frequency distributions of landing were available for 2002 and for all years of OTB-MDDWSP.

In GSA 5, no length frequency distributions of landing were available for 2016 and for 2009 of OTB-MDDWSP.

In GSA 6, no length frequency distributions were available for all years of OTB-MDDWSP. The length frequency distribution in 2015 had an extremely high number of individuals in the length class 33.
In GSA 7, only the length frequency distributions of landing for Spanish OTB were available. They cover the period 2009-2018. No length frequency distributions of landing were available for OTBMDDWSP.

Length and age frequency distributions of the discards were not available in the DCF data.
Issues with the MEDITS data in GSA 1 were pointed out. The TC in 2013 contains two hauls ( 16 and 38) with wrong values in "pfrac". The correct values (854 and 261 g , respectively) were
recovered from "pechan". The numbers of individuals were also corrected in TB, finding them from TC.

In the MEDITS data of GSAs 1,6 and 7 there are animals of lengths higher than 50 mm carapax length, which were considered wrong.

The MEDITS length frequency distributions in GSA 5 for 2001 should be checked thoroughly because are considered to be wrong.

### 6.3 Red Mullet in GSA 1

### 6.3.1 Stock Identity and Biology

Due to a lack of information about the structure of red mullet population in the western Mediterranean, this stock was assumed to be confined within the GSA 1 boundaries

Figure 6.3.1.1 Geographical location of GSA 1
Red mullet is among the most important target species for the trawl fisheries but is also caught with set gears, in particular trammel-nets (about the $12 \%$ of the catches). From official data, the total trawl fleet of the geographical sub-area GSA 1 (Northern Alboran Sea region) is composed by about 170 boats (data compiled in EWG 11-12). Smaller vessels operate almost exclusively on the continental shelf (targeting red mullets, octopus, hake and sea breams), bigger vessels operate almost exclusively on the continental slope (targeting decapod crustaceans) and the remaining can operate indistinctly on the continental shelf and slope fishing grounds. Red mullet is intensively exploited during its recruitment from August to November.

Trawl fisheries in GSA 1 are regulated by "Orden AAA/2808/2012" published in the Spanish Official Bulletin (BOE no 31329 December 2012) containing an Integral Management Plan for Mediterranean fishery resources. To the traditional fisheries regulations already in place (e.g. the daily and weekly fishing effort limited to 12 hours per day five days a week; trawl cod end 40 mm square mesh or 50 mm diamond stretched mesh; engine power of maximum 373 kW ; license system; minimum landing size of 11 cm TL ).
Minimum landing size for red mullet is established at 11 cm TL from the CE Regulation 1967/2006.
The Von Bertallanfy growth parameters estimated within the Spanish DCF considered to have a very low $\mathrm{t}_{0}$, (STECF EWG 12 - 02) and thus, the STECF EWG 19-10 decided to use the ones selected during EWG $15-06$ meeting ( $\mathrm{Linf}=34.5, \mathrm{k}=0.34, \mathrm{t} 0=-0.143$ ) with a 0.5 added in the $\mathrm{t}_{0}$
according to the suggestions of the EWG in order to align the growth correctly with the length slice based on the calendar year Jan-Dec. Length - weight parameters ( $a=0.0102, b=3.03$ ) were derived from Spanish DCF for the year 2007 for sexes combined and total length expressed in cm . These parameters were used in the statistical catch at age assessment (a4a).

A vector of natural mortality was estimated by Chen Watanaby method (Chen S. \& Watanabe S., 1989) using growth and length-weight relationship parameters for sex combined.

The species reaches sexual maturity at one year old the vector of maturity at age was provided by the experts of the EWG 19-10.

Table 6.3.1.1 Red mullet GSA 1. Maturity and natural mortality.

| Age | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4 +}$ |
| :---: | :---: | :---: | :---: | :---: |

Landings for MUT in GSA 1 by Gear

Figure 6.3.2.1.2 Total landings by year and gear for Red mullet in GSA 1 .

Length frequency distributions of the landings by year and by fleet and year for the Red mullet are presented in figures 6.3.2.1.3 and 6.3.2.1.4

## Length stracture by year MUT GSA 1

Figure 6.3.2.1.3 Length frequency distribution of Red mullet landings in GSA 1.

Length frequency distribution of Red mullet in GSA 1 in 2012 provided by the Spanish DCF was wrong. A corrected version was provided by Spanish experts during the EWG, only LFD for the OTB, which was used in the assessment.

Figure 6.3.2.1.4 Length frequency distribution of Red mullet landings by year and gear in GSA 1.

## DISCARDS

Discards of Red mullet in GSA 1 provided by the Spanish DCF. Discards for Red mullet in GSA 1 considered to be negligible due to very low percentage in catch and also due to misreporting especially in the beginning of the time series. The highest percentage in the catch is reported in 2016 with a $3 \%$ and the average throughout the years is $1 \%$. Also no length frequency distribution was provided from the Spanish DCF except for the years 2017 and 2018.

Table 6.3.2.1.2 Red mullet GSA 1. Discards by year.

| year | discards |
| :--- | :---: |
| 2008 | 0.16 |
| 2009 | 1.09 |
| 2010 | 0.01 |
| 2011 | 0.13 |
| 2012 | 1.65 |
| 2013 | 0.28 |
| 2014 | 3.28 |
| 2015 | 1.76 |
| 2016 | 7.61 |
| 2017 | 3.48 |
| 2018 | 2.79 |

Discards for MUT by gear in SA 1

Figure 6.3.2.1.6 Red mullet in GSA 1. Discards by year and gear.

Spanish DCF reported length frequency distribution of discarded Red mullet only for the years 2017 and 2018.

Figure 6.3.2.1.7 Red mullet in GSA 1. Discards length frequency distribution by year and gear.

### 6.3.2.2 EfFORT

Red mullet is caught by mixed fisheries, using a variety of fishing gears ( trammel nets, trawls), by fishing boats of different sizes and metiers. Although the main bulk of the catch comes from the trawlers. In such situation, red mullet is only one component of entire catch, fishing effort specifically related to red mullet only cannot be obtained independent of other fisheries.

### 6.3.2.3 SURVEY DATA

Since 1994, MEDITS trawl surveys has been carried out during the end of spring - beginning of the summer season, as part of the DCF National Program. In the current assessment, for the a4a method, MEDITS data from 2004 onwards were used. MEDITS survey was not reported for the year 2011 and there were some inconsistencies with the data for the year 2006, due to some incorrect raising factor reported in the MEDITS TB file, these have been corrected.
The sampling design of MEDITS is random stratified sampling with number of hauls by stratum proportional to stratum surface. Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Hauls noted as valid were used only, including stations with no catches (zero catches are included). Based on the DCF data call, abundance and biomass indices were calculated.
Observed abundance and biomass indices of Red mullet and the length frequency distributions are given on the figures below (Figures 6.2.2.3.1-6.2.2.3.2-6.2.2.3.3). Both estimated abundance and biomass indices show similar stable trends throughout the years with a peak through years 2006-2009.

Figure 6.3.2.3.3. Red mullet in GSA 1. Length frequency distribution for the MEDITS index for the years 1994-2018.

### 6.3.3 StOCK ASSESSMENT

STECF EWG 19-10 was asked to assess the status of Red mullet in GSA 1. Only one method was used to assess the status of Red mullet, a statistical catch at age method.

## A4a

Assessment for all Initiative (a4a) (Jardim et al., 2015) is a statistical catch - at - age method that utilize catch at age data to derive estimated of historical population size and fishing mortality. Model parameters are estimated by working forward in time and analyses do not require the assumption that removals from the fishery are known without error. A4a is implemented as a package (Fla4a) of the FLR library.

## Input data

The a4a model was carried out using as input catch data from 2004 to 2018 due to misreported length frequency distribution of catch in 2003. For the tuning fleet, MEDITS survey was used for the years 2004-2018.

Catch numbers at age and index numbers at age were derived by slicing the catch numbers at length and index numbers at length respectively. For the slicing procedure the I2a routine of FLR was used. The growth parameters for the slicing are reported in table (6.2.1.1) and were chosen as the most suitable for this species and this area.

Sum of Products (SoP) correction was applied in catch numbers at age to match the total catch by year reported in the DCF. Most of the years the SoP varies between $3-10 \%$ but in the year 2012 the value seem very high probably due to the misreported length frequency that year.

Table 6.3.3.1 Red mullet in GSA 1. Sum of Products correction array.

| year | $\mathbf{2 0 0 3}$ | $\mathbf{2 0 0 4}$ | $\mathbf{2 0 0 5}$ | $\mathbf{2 0 0 6}$ | $\mathbf{2 0 0 7}$ | $\mathbf{2 0 0 8}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| SoP | 1.01 | 1.03 | 0.93 | 0.99 | 0.89 | 0.89 |
| year | $\mathbf{2 0 0 9}$ | $\mathbf{2 0 1 0}$ | $\mathbf{2 0 1 1}$ | $\mathbf{2 0 1 2}$ | $\mathbf{2 0 1 3}$ | $\mathbf{2 0 1 4}$ |
| SoP | 0.94 | 0.98 | 0.94 | 1.67 | 1.03 | 0.94 |
| year | $\mathbf{2 0 1 5}$ | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 7}$ | $\mathbf{2 0 1 8}$ |  |  |
| SoP | 0.96 | 1.05 | 1.03 | 0.90 |  |  |

The following tables lists the input parameters to the a4a, namely catches, catch numbers at age, mean weight at age, natural mortality at age, maturity at age and proportion of F and M before spawning, along with their figures.

Table 6.3.3.2 Red mullet in GSA 1. Total catch by year.

For the tuning index of the a4a method the STECF EWG decided to use the MEDITS abundance index for the period 2004 - 2018 in order to correspond to the existing data for the distribution of catches at age. Age slicing was also performed to the length frequency distribution of abundance index. The following table presents the estimated numbers at age for the MEDITS tuning index.

Figure 6.3.3.4. Red mullet in GSA 1. Survey index at age for the years $2004-2018$

## Assessment Results

Different a4a models were investigated in terms of fishing mortality, catchability of the survey index and stock - recruitment relationship models (fmodel, qmodel, srmodel). Smoothing splines were essential in fitting a model.
The following model was selected on the basis of best fit, both for residuals as well as fitted vs observed data and retrospective; this model also coincides with the general perception of the STECF EWG on fishing mortality allocation throughout age groups, as well as on the catchability of the index.
qmod <- list( $\sim$ factor(replace(age, age>2, 2)))
fmod1 <-~ s(age, $k=3)+s(y e a r, k=7)$
srmod <- ~ s(year,k=7)

The following figure presents the summary of the stock object after the fit of the model. The recruitment, spawning stock biomass catch and fishing mortality.

Figure 6.3.3.5. Red mullet in GSA 1. Stock summary from the a4a model for Red mullet in GSA 20, recruits, SSB (Stock Spawning Biomass), catch and harvest (fishing mortality for ages 1 to $3)$.

The following plots present estimated fishing mortality by age and year and estimated catchability by age and year.

Fishing mortality

Figure 6.3.3.6. Red mullet in GSA 1. 3D contour plot of estimated fishing mortality by age and year.

Figure 6.3.3.7. Red mullet in GSA 1. 3D contour plot of catchability by age and year.

Several diagnostic plots presented below for the goodness of fit of the selected model for the assessment of Red mullet stock. Residuals of index showed a slight descending trend especially for the ages 2 and 3, due to the constraint of index catchability model. EWG 19-10 considered the fact that there is a trade of between a better fit and the best representative model of the catchability of the survey, and used a flat catchability ages 2 and 3 for the index.

### 6.3.4 Reference Points

Due to the short time series full evaluation of reference points is not possible, and recent equilibrium values are used. In Red mullet assessment in GSA 1, Fo.1 has been considered as the best proxy of Fmsy reference point. Fo.1 had been calculated using the FLBRP package of the FLR library on the assessment results. FLBRP allows Yield per Recruit analysis and the estimation of f based reference points. Using the assessment the value of $\mathrm{F}_{0.1}$ was calculated equal to 0.54 .

### 6.3.5 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2020 to 2021 was performed using the FLR routines provided by JRC and based on the results of the a4a stock assessments performed during EWG 19-10.

The input parameters for the STF were taken following the procedure in Section 4.3 Table 6.1.5.1. The input parameters for selection, mean weights, maturity and natural mortality were means of the last three years from the a4a stock assessment and its results. $F$ status quo for
$F_{2019}$ is equal to $F_{2018}$, equal to 2.10 and corresponding to a catch 2019 of $99 t$. Recruitment was estimated to be 8335 and was calculated as geometric mean of all the years of the time series. STF results are given table 6.3.5.2 for a range of options between 0 and $\mathrm{F}=2$ *F2018

Table 6.1.5.1 Red Mullet in GSAs 1: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |

[^5]
### 6.3.6 DATA Deficiencies

EWG 19-10 decided not to include year 2003 in the assessment input due to some inconsistencies reported in the length frequency distribution of landings. Scientists from the corresponding country (Spain) agreed that being the first year of sampling for the DCF, the reported values are incomplete or misreported. Discards data were also incomplete and misreported for several years. Gaps appeared throughout the years 2003-2007 and 2010. Length frequency distribution for the discards reported only for 2017 and 2018. Inconsistencies were also apparent in the MEDITS Survey Index for the year 2006 and the year 2011 was missing. Standardized length frequency distribution was recalculated for this year.

According to ToR 9, the EWG19-10 reported on line via the Data Transmission Monitoring Tool (DTMT) available at https://datacollection.jrc.ec.europa.eu/web/dcf/dtmt.

The EWG18-12 also summarized and concisely described catch and effort data deficiencies, in terms of coverage and quality.

### 6.4 Striped Red Mullet in GSA 5

### 6.4.1 Stock Identity and Biology

GSA 5 (Figure 6.4.1.1) has been pointed as an individualized area for assessment and management purposes in the western Mediterranean (Quetglas et al., 2012) due to its main specificities. These include: 1) Geomorphologically, the Balearic Islands (GSA 5) are clearly separated from the Iberian Peninsula (GSA 6) by depths between 800 and 2000 m , which would constitute a natural barrier to the interchange of adult stages of demersal resources; 2) Physical geographically-related characteristics, such as the lack of terrigenous inputs from rivers and submarine canyons in GSA 5 compared to GSA 6, give rise to differences in the structure and composition of the trawling grounds and hence in the benthic assemblages; 3) Owing to these physical differences, the faunistic assemblages exploited by trawl fisheries differ between GSA 5 and GSA 6, resulting in large differences in the relative importance of the main commercial species; 4) There are no important or general interactions between the demersal fishing fleets in the two areas, with only local cases of vessels targeting red shrimp in GSA 5 but landing their catches in GSA 6; 5) Trawl fishing exploitation in GSA 5 is much lower than in GSA 6; the density of trawlers around the Balearic Islands is one order of magnitude lower than in adjacent waters; and 6) Due to this lower fishing exploitation, the demersal resources and ecosystems in GSA 5 are in a healthier state than in GSA 6 , which is reflected in the population structure of the main commercial species (populations from the Balearic Islands have larger modal sizes and lower percentages of small-sized individuals), and in the higher abundance and diversity of elasmobranch assemblages.

Figure 6.4.1.1. Geographical localization of GSA 5.

The biological parameters, natural mortality vector and maturity ogive used for the assessment of M. surmuletus were those shown in the following tables. Growth parameters (Table 6.4.1.1) were those used in the last assessment of this stock carried out by the Working Group of Stock Assessment of Demersal Species of the General Fisheries Commission for the Mediterranean (GFCM), from Campillo (1992). Length-weight relationship was obtained from the Data Collection. For to, 0.5 has been added in order to adjust the curve as the spawning period of the species is in
spring and not at the beginning of the year. Natural mortality (Table 6.4.1.2) has been calculated using PRODBIOM. Proportion of matures (Table 6.4.1.3) has been set considering all the individuals become mature in age 1.

Table 6.4.1.1. Mullus surmuletus in GSA 5. Growth and length-weight parameters.

| Growth |  |

### 6.4.2 DATA

## General description of the fisheries

In the Balearic Islands (western Mediterranean), commercial trawlers develop up to four different fishing tactics, which are associated with the shallow shelf, deep shelf, upper slope and middle slope (Guijarro and Massutí 2006; Ordines et al. 2006), mainly targeted to: (i) Spicara smaris, Mullus surmuletus, Octopus vulgaris and a mixed fish category on the shallow shelf ( $50-80 \mathrm{~m}$ );
(ii) Merluccius merluccius, Mullus spp., Zeus faber and a mixed fish category on the deep shelf ( $80-250 \mathrm{~m}$ ); (iii) Nephrops norvegicus, but with an important by-catch of big M. merluccius, Lepidorhombus spp., Lophius spp. and Micromesistius poutassou on the upper slope (350-600 m) and (iv) Aristeus antennatus on the middle slope (600-750 m). The striped red mullet, M. surmuletus, is one of the target species in the shallow shelf.

## Management regulations

- Fishing license: number of licenses observed
- Engine power limited to 316 KW or 500 HP: not fully observed.
- Mesh size in the cod-end (before Jun 1st 2010: 40 mm , diamond: after Jun 1st 2010: 40 mm square or 50 mm diamond -by derogation-): fully observed.
- Time at sea ( 12 hours per day and 5 days per week): fully observed.
- Minimum landing size (EC regulation $1967 / 2006,11 \mathrm{~cm}$ TL): mostly fully observed catch.

### 6.4.2.1 CATCH (LANDINGS AND DISCARDS)

Landings for striped red mullet in GSA 5 come both from bottom trawlers and trammel nets, with bottom trawlers representing around $80-90 \%$ of total landings. Following a reduction in 20072009, since 2013 an increase in bottom trawl catches is observed (Figure 6.4.2.1).

Figure 6.4.2.1. Mullus surmuletus in GSA 5. Reported Landings from the DCF Data call by gear.

Discards for this stock can be considered as neliglible and catches are assumed to be equal to landings.
Length frequency distribution for the striped red mullet in GSA 5 shows differences between métiers, with trammelnets targetting larger individuals than bottom trawlers (Figure 6.4.2.2). Age composition is mainly formed by age 1 individuals, although age 0 and age 2 are also frequent in the catches (Figure 6.4.2.3). Cohorts showed a good consistency, especially for the youngest classes (figure 6.4.2.4).

Figure 6.4.2.2. Striped red mullet in GSA5. Catch length frequency distribution, by year and métier (TL cm).

Figure 6.4.2.3. Striped red mullet in GSA 5. Catch-at-age.

## Cohorts consistence in the catch

Figure 6.4.2.4. Striped red mullet in GSA 5. Cohort consistency for the commercial catches.

### 6.4.2.2 EfFORT

Fishing effort, as days at sea, by fishing gear (OTB and GTR) is shown in Figure 6.4.2.5 and Table 6.4.2.1. These values correspond to all the fishing trips from these gears, not to those days directed to the catch of this species. Both for 2007 and 2008, values are consideribly lower than the rest of the data series and thus this should be checked (see Quality section). There are some French landings reports assigned to this GSA which may be an error than should be reviewed.

Figure 6.4.2.5. Fishing effort (in fishing days) for the fleet operating in GSA 5: trawlers (OTB) and trammel net (GTR).

### 6.4.2.3 SURVEY DATA

The MEDITS (MEDiterranean International Trawl Survey) survey is an extensive trawl survey occurring in all European countries and included in the Data Collection Framework. According to the MEDITS protocol (Bertrand et al., 2002), it takes places every year during springtime following a random stratified sampling by depth (5 strata: 0-50 m, 50-100 m, 100-200 m, 200500 m and over 500 m ). The number of hauls in each stratum is proportional to the surface of the stratum and their positions were randomly selected and maintain fixed throughout the time. Same sampling gear (GOC73), characterized by a 20 mm stretched mesh size cod-end is used throughout GSAs and years.

MEDITS survey started in GSA 5 in 2007. Before 2007, data were collected for only a few stations, so these years are considered non representative. Mean stratified abundances and biomasses by $\mathrm{km}^{2}$ has been computed using the methodology described by Grosslein and Laurec (1982).

Density and biomass indices showed variations along the data series, with high values for 2007 and 2017 (Figure 6.4.2.6). Due to the large variability found in the indices for some of the years, their variance were included in the assessment in order to weight the data. Length frequency distributions are shown in Figure 6.4.2.7 and table 6.4.2.2. Age composition of the catches from the survey showed that most of the individuals correspond to age 1, although age 2 is also important (Figure 6.4.2.8). Cohorts showed no consistency (Figure 6.4.2.9).

Figure 6.4.2.6. Striped red mullet in GSA 5. MEDITS abundance ( $\mathrm{n} / \mathrm{km}^{2}$ ) and biomass ( $\mathrm{kg} / \mathrm{km}^{2}$ ) indices over 2007-2018.

### 6.4.3 StOCK ASSESSMENT

Striped red mullet in GSA 5 was assessed with XSA (Method 1) and a4a (Method 2). Advice and short term forecast are given based on a4a.

## Method 1: XSA

Input data come from the DCF. Striped red mullet catches, natural mortality and maturity at age are presented in previous sections. Slicing of the LFDs was done considering both sexes combined, using L2AGE4. A SOP correction was applied to the original catch data.

Several sensitivity analyses were performed before the final XSA run, considering different combinations for shrinkage (Figure 6.4.3.1). The final settings considered were the following:

| fse | Rage | qage | shk.n | shk.f | shk.yrs | shk.ages |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1.5 | 0 | 3 | TRUE | TRUE | 3 | 2 |

Figure 6.4.3.1. Striped red mullet in GSA 5. XSA sensitivity analyses consdering different combinations for shrinkage.

Residuals showed high values for age 4 but not a significant trend for any of the ages, and low values for the rest of the ages (Figure 6.4.3.2). Retrospective analysis did not show any trend (Figure 6.4.3.3).

Log residuals for surveys for Mullus surmuletus in GSA 5

Figure 6.4.3.2 Striped red mullet in GSA 5. Residuals pattern of MEDITS survey residuals at age $4+$ in 2014,2015 and 2016 are from dummy values set arbitrarely to 0.001 .

Figure
6.4.3.3 Striped red mullet in GSA5. XSA retrospective analysis.

XSA results for striped red mullet in GSA5 showed a clear decreasing tren for the last years and an increasing trend in recruitment and SSB (Figure 6.4.3.4, Table 6.4.3.1).

Figure 6.4.3.4. Striped red mullet in GSA 5. XSA assessment summary results.
Table 6.4.3.1. Striped red mullet in GSA 5. XSA assessment summary results. Biomass, catch and SSB in tonnes, recruits in thousands, Fbar ages 1-2.

|  | Biomass | Catch | SSB | Recruits | Fbar |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2002 | 494.5 | 131.7 | 276.8 | 10884.7 | 1.43 |
| 2003 | 519.8 | 101.6 | 261.1 | 15217.4 | 1.01 |
| 2004 | 603.8 | 152.9 | 349.4 | 12719.6 | 1.11 |
| 2005 | 575.7 | 148.5 | 346.0 | 12085.9 | 1.10 |
| 2006 | 559.6 | 152.9 | 334.4 | 14078.2 | 1.22 |
| 2007 | 526.5 | 170.1 | 352.4 | 9161.4 | 1.43 |
| 2008 | 431.0 | 139.2 | 268.4 | 8130 | 1.66 |
| 2009 | 364.7 | 73 | 200.4 | 9130 | 0.88 |
| 2010 | 394.8 | 93.2 | 244.7 | 7904.3 | 0.91 |
| 2011 | 404.9 | 107.4 | 242.2 | 9038.1 | 1.18 |
| 2012 | 390.4 | 100.4 | 244.8 | 7277.5 | 1.06 |
| 2013 | 374.8 | 87.9 | 228.5 | 6963.8 | 0.95 |
| 2014 | 373.3 | 95.3 | 224.3 | 7453.5 | 1.14 |
| 2015 | 395.4 | 96.6 | 216.0 | 9961.5 | 1.21 |
| 2016 | 446.6 | 106.5 | 244.0 | 11259.2 | 1.15 |
| 2017 | 574.1 | 109.9 | 277.5 | 15610.6 | 0.98 |
| 2018 | 621.6 | 132.4 | 414.8 | 9844 | 0.74 |

From XSA results, Fref, $1-2$ in the last years $(2016-2018)=0.96$; and $\mathrm{F}_{0.1}=0.42$ (from YpR). According to these values, $\mathrm{F} / \mathrm{F}_{0.1}=2.3$, thus, the stock is considered overexploited.

Method 2: a4a

Assessment for All Initiative (a4a) (Jardim et al., 2015) is a statistical catch-at-age method that utilize catch at age data to derive estimated of historical population size and fishing mortality. Model parameters are estimated by working forward in time and analyses do not require the assumption that removals from the fishery are known without error. A4a is implemented as a package (FLa4a) of the FLR library.

## Input data

The a4a model was carried out using as input survey and catch the same input as the XSA method presented previously.

## Assessment Results

Different a4a models were investigated in terms of fishing mortality, catchability of the index and stock-recruitment relationship models (fmodel, qmodel, srmodel). The following model was selected on the basis of best fit, both for residuals as well as fitted vs observed data and retrospective; this model also coincides with the general perception of the STECF EWG on fishing mortality allocation throughout age groups, as well as on the catchability of the index.

```
qmod <- list( \(\sim\) factor(replace(age,age>2,2)))
fmod <- ~ s(replace(age,age>2,2), k=3) + s(year,k=6)
srmod <- ~factor(year)
```

Figure 6.4.3.5 and Table 6.4.3.2 show the summary of the stock object after the fit of the model. F shows a clear decreasing trend in the last two years. Recruitment showed the highest values in 2017 and the lowest in 2018. SSB showed an increasing trend in the last year.

Figure 6.4.3.5. Striped red mullet in GSA 5. Stock summary from the a4a model: recruitmend (thousands), SSB (Stock Spawning Biomass, tonnes), catch (tonnes) and fishing mortality for ages 1 to 2).

Figure 6.4.3.6 and 6.4.3.7 show the estimated fishing mortality by age and year and estimated catchability by age and year, respectively.

Table 6.4.3.2. Striped red mullet in GSA 5. Summary results of the estimations from the a4a assessment model. Biomass, catch and SSB in tonnes, recruits in thousands, Fbar ages 1-2.

|  | Biomass | Catch | SSB | Recruits | Fbar |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2007 | 442.6 | 169.0 | 295.8 | 7727.0 | 1.58 |

## fitted and observed index-at-age

Figure 6.4.3.11. Striped red mullet in GSA 6. Fitted and observed index at age

## RETROSPECTIVE

The retrospective analysis was applied up to 3 years back (Figure 6.4.3.12). They shown an underestimation trend for recruitment and SSB and an overestimation for $F$, probably due to the short data series available.

Figure 6.4.3.12. Striped red mullet in GSA 5. Retrospective analysis for the a4a model.

## SIMULATIONS

Figure 6.4.3.13 shows the simulations carried out for striped red mullet in GSA 5.

Figure 6.4.3.13. Striped red mullet in GSA 5. Stock summary of the simulated and fitted data for the a4a model.

## Comparison between XSA and a4a

Figure 6.4.3.14 show the results for XSA and a4a models. They showed very similar valules in all cases, except for recruitment in the last two years, SSB in the last year and $F$ in the last 4 years, in which a4a showed lower values than XSA. The a4a model assumes that $F$ is separable and consistent over age in recent years, in contrast XSA assumes $F$ at age varies and $F$ is maintained closer to the long term mean. These differences give the different conclusions in the last two years. While it is not possible to be certain which approach is correct, the retrospective in a4a does not suggest repeated underestimation of $F$, rather the opposite. Overall it was decided to use the a4a model. Overall it must be considered that the terminal $F$ is uncertain.

Figure 6.4.3.14. Striped red mullet in GSA 5. Results for the XSA and a4a models: recruitmend (thousands), SSB (Stock Spawning Biomass, tonnes), catch (tonnes) and fishing mortality for ages 1 to 2).

### 6.4.4 Reference Points

The assessment is considered suitable for full evaluation of FMSY. In the assessment of striped red mullet in GSA 5, $\mathrm{F}_{0.1}$ has been considered as the best proxy of FMSY reference point. F $\mathrm{F}_{0.1}$ had been calculated using the FLBRP package of the FLR library on the assessment results, with a value of 0.39. FLBRP allows Yield per Recruit analysis and the estimation of f-based reference points. Using the assessment the value of $F_{0.1}$ was calculated equal to 0.42 .

### 6.4.5 Short term Forecast and Catch Options

A short term forecast was carried out following the parameter choices given in section 4.3. Three year mean values for mean weights, maturity, natural mortality and selection were taken from the last three years of the assessment. Due to the clear decreasing trend of F during the last 2 years, status quo F was calculated as the last year. Recruitment 2018 and 2019 was estimated as the geometric mean of the timeseries. Table 6.4.5.1 summarizes the results of the short term forecast.

Table 6.1.5.1 Striped red mullet GSAs 5: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological Parameters |  | mean weights at age, maturation at age, natural mortality at age <br> and selection at age, based average of 2016-2018 |
| Fages 1-2 $(2019)^{\text {and }}$ (2019) | 0.39 | F2018 used to give F status quo for 2019 |
| SSB | 468 | Stock assessment 1 January 2019 |
| $\mathrm{R}_{\text {age0 }}(2019,2020)$ | 8081 | Geometric mean of the time series years |
| Total catch (2019) | 133 | Assuming F status quo for 2019 |

### 6.5 Red MULLET IN GSA 6

### 6.5.1 Stock Identity and Biology

Red mullet, benthic species that inhabits coastal waters, is among the main demersal fishing target species in the Mediterranean fisheries. Its fishing displays characteristics which typically define the Mediterranean fisheries, that is, marked seasonality, strong dependence on recruitment, and exploitation based on a very small number of age classes, basically age classes 1 and 2.
The red mullet's genetic distribution was found to be highly structured, resembling that of a meta-population composed by independent, self-recruiting sub-populations with some connections between them. This species showed significant genetic differentiation across Cabo de Gata (GSA 1)- Blanes (northern GSA 6)- Italy (GSA 9) comparisons (Galarza et al. 2009).

Gonadal maturation and spawning take place in late spring (May-June in the western Mediterranean). Larvae are found in the plankton during June-July in the upper levels of the water column, above thermocline. Horizontal and vertical distribution of larvae showed good correspondence with that of cladocera, their preferential prey from 8 mm standard length. Prey items consumed by the smallest size classes of larvae $<8 \mathrm{~mm}$ SL were dominated by copepod nauplii, then diet and prey selectivity shifted towards the cladoceran Evadne spp. (Sabatés and Palomera 1987; Sabatés et al. 2015).
M. barbatus is a batch spawner with an income breeding strategy (continues feeding throughout the spawning period), an asynchronous development of oocytes and indeterminate fecundity (Ferrer-Maza et al. 2015). Recruitment to the benthic life on coastal bottoms takes place during a well-defined season, in summer and early autumn (Lloret and Lleonart, 2002), in relation to the short spawning period. The maximum abundance and frequency of pre-adults and adults occurs on muddy bottoms in waters between 50 and 200 m deep (Lombarte et al. 2000). Red mullet feeds on small benthic crustaceans, worms and molluscs (Hureau 1986). Size groups (that correspond to different cohorts) are concentrated in specific areas. The massive presence of the O+ year class, very close to the coast immediately after recruitment to the bottom (in late summer) is followed by a dispersal towards deeper waters (Suau and Vives 1957; Voliani et al 1998).

## Maturity

Red mullet has a short spawning period of around two months (May-June). The EWG assumed that age 0 corresponds to juveniles and at age1 all individuals will spawn, that is, are mature the spawning season following the spawning season when they were born.

The growth parameters submitted by the MS did not fit the observed length-at-first maturity and spawning timing because of the very negative to values. After discussion, the growth parameters proposed by Demestre et al. 1997 were selected to be used in the assessment of the stock ( $\operatorname{Linf}=34.5, \mathrm{k}=34, \mathrm{t}_{0}=-0.14$ ). In addition, since the red mullet spawning takes place in the middle of the year, the growth curve was corrected for a calendar year assessment (t0 +0.5). The parameters of the length-weight relationship were $a=0.0096$ and $b=3.04$ (DCF (2017), the same as used in the previous EWG18-12 assessment).

Natural mortality vector
M vector was estimated with the method proposed by Chen and Watanabe (1989).

| age | 0 | 1 | 2 | 3 | 4 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| M | 1.74 | 0.80 | 0.57 | 0.48 | 0.43 |

### 6.5.2 DATA

Red mullet landings in GSA 6 come predominantly from OTB; a small amount is reported for small-scale fishing gears (trammel-net). Landings from small-scale gears other than entangling nets may be a mistake when coding the fishing gear.

### 6.5.1.1 Catch (landings and discards)

Table 6.5.2.1.1 Red mullet in GSA 6. Landings by fishing gear over 2002-2017 (tonnes; FPO=pots and traps; GNS=gillnet; GTR=trammel net; LLS=longline; OTB=otter bottom trawl).

### 6.5.1.3 Survey data

Survey indices used in this assessment originate from the MEDITS bottom trawl survey. This survey was carried out regularly in late spring, in May-June, over the period 1994-2018 (Fig. 6.5.2.3.1).

Figure 6.5.2.3.1 MEDITS survey periods in GSA 6 .

### 6.5.3 STOCK ASSESSMENT

Assessment for All Initiative (a4a) (Jardim et al., 2015) is a statistical catch-at- age method that utilize catch at age data to derive estimates of historical population size and fishing mortality was used to assess this stock. Model parameters are estimated by working forward in time and analyses do not require the assumption that removals from the fishery are known without error. A4a is implemented as a package (Fla4a) of the FLR library.

Input data growth parameters, total catch, numbers at age, natural mortality $M$, maturity at age and survey index are given in previous sections. Fbar was $F(1-3)$.

## Assessment Model Settings

Different a4a models were performed (combination of different f, q and sr). The following model was selected, according to residuals and retrospective:

```
fmodel: ~s(replace(age, age > 2, 2), k = 3) + s(year, k = 6)
srmodel: ~s(year, k = 7)
qmod <- list(~ factor(replace(age, age>2, 2)))
```

## Assessment Results

## Stock Summary

Figure 6.5.3.1 Red mullet in GSA 6. Stock summary from the a4a model for Red mullet in GSA 6 , recruits, SSB (Stock Spawning Biomass), catch and harvest (fishing mortality for ages 1 to 3).

Fishing mortality

Figure 6.5.3.2 Red mullet in GSA 6. 3D contour plot of estimated fishing mortality by age and year.

## Catchability

Figure 6.5.3.3 Red mullet in GSA 6. 3D contour plot of estimated fishing mortality by age and year.

## Diagnostics

Several diagnostic plots presented below for the goodness of fit of the selected model for the assessment of Red mullet stock.
log residuals of catch and abundance indices by age

| 2014 | 486290 | 1372.4 | 1378.5 | 1.376 |
| 2015 | 519961 | 1409.1 | 1443.1 | 1.354 |
| 2016 | 535441 | 1538.6 | 1515.8 | 1.352 |
| 2017 | 494659 | 1448.9 | 1583.0 | 1.390 |
| 2018 | 415681 | 1335.9 | 1597.5 | 1.462 |

Overall the assessment provides consistent if not very precise perception of the stock. The residuals are variable with some minor cohort effects. The restrospectives are relatively stable and the conclusions on stock status are similar across years. $F$ is consistemntly estimated to be 3 to 4 times $\mathrm{F}_{\text {MSY }}$ (see section 6.5.4) Catches are estimated to be significantly higher in 2009 and 2010 and lower in 2005 and 2006, but in recent years catch estimates are within intervals (Figure 6.5.3.9). In recent years catches, recruit, SSB but also F are found to be high (Figure 6.5.3.9).

### 6.5.4 Reference Points

The time series is too short to give stock recruitment rationship, so reference points are based on equilibrium methods. The STECF EWG 18-02 recommended to use $\mathrm{F}_{0.1}$ as proxy of Fmsy. The library FLBRP available in FLR was used to estimate $F_{0.1}$ from the stock object resulting from the outputs of the a4a assessment. Fo.1 ages $1-3$ is estimated to be 0.313

### 6.5.5 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the a4a stock assessment.

The basis for the choice of values is given in Section 4.3. An average of the last three years has been used for weight at age, maturity at age, while the $\mathrm{F}_{\mathrm{bar}}=1.46$ terminal F (2018) from the a4a
assessment was used for F in 2019. Recruitment is observed to be higher in the later part of the timeperiod of the assessment (Figure 6.5.3.1) so only recent recruitment is used as an estimate of recruits in 2019 and 2020. Recruitment (age 0) for 2019 to 2021 has been estimated from the population results as the geometric mean of the last 6 years (484531.7).

Table 6.5.5.1 Red mullet GSA 6: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological <br> Parameters |  | mean weights at age, maturation at age, natural mortality <br> at age and selection at age, based average of 2016-2018 |
| Fages 1-3 (2019) | 1.46 | F2018 used to give F status quo for 2019 |
| SSB (2019) | 1335.9 | Stock assessment 1 January 2019 |
| $R_{\text {ageo }(2019,2020)}$ | 484532 | Geometric mean of the last 6 years (2013-2018) |
| Total catch (2019) | 1438 | Assuming F status quo for 2019 |

Table 6.5.5.1 Red mullet GSA 6. Short term forecast in different $F$ scenarios.

*SSB at mid year

### 6.5.6 DATA Deficiencies

A change in the coding of the métiers was observed in 2010 and 2018.
MEDITS length frequencies distributions should be checked for sizes 10 and 60. The value in these sizes is systematically 0 , over the whole period 1994-2018, even in cases when sizes $>60$ are recorded.

### 6.6 Red Mullet in GSA 7

### 6.6.1 Stock Identity and Biology

Red mullet (Mullus barbatus) in the Gulf of Lions (GSA 7) is a shared stock exploited by both Spanish and French trawlers, and since 2011 also by French artisanal gears.

The growth parameters used in the present assessment are fast growth parameters sex combined from Demestre et al. (1997) and used in the recent assessment (GFCM, 2017), STECF 18-12. Lenght-weight relation ship is also the used in the
recent assessment (GFCM, 2017), STECF 18-12 (Table 6.6.1.1).

Table 6.6.1.1 Red mullet in GSA7. Von Bertalanffy growth paramenters and length-weight relationship.

| Von <br> Bertalanffy | Sex <br> Combined | Length-weight <br> relation ship |  |
| :--- | :--- | :--- | :--- |
| Linf $(\mathrm{cm})$ | 34.5 | a | 0.0064 |
| $\mathrm{k}($ years -1$)$ | 0.34 | b | 3.18 |
| $\mathrm{t}_{0}$ | -0.14 |  |  |

Maturity (table 6.6.1.2) was calculated assuming that spawning red mullet season is very short (May-June) and young individuals reach maturity when arrive to Age 1 on 1st of January. For ages $>1$ all individuals are considered adults.

Natural mortality (table 6.6.1.2) was obtained from Rscript provided during the meeting and it is based on Chen Watanabe formula.

Table 6.6.1.2 Red mullet in GSA7. Maturity and M (natural mortality) vectors

| Age | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3 +}$ |
| :--- | :--- | :--- | :--- | :--- |
| Maturity | 0 | 1 | 1 | 1 |
| M | 1.74 | 0.80 | 0.57 | 0.48 |

### 6.6.2 Data

Available catch, landing and discards data are from DCF. EWG 19-10 received French and Spanish data for GSA 7 by fishing gears. French data are provided since 2002 to 2017 and Spanish data are provided since 2004 to 2017. Data used in EWG 18-12 are for the period from 2004 to 2017.

### 6.6.2.1 CATCH (LANDINGS AND DISCARDS)

Total catch by year is reported in table 6.6.2.1.1 (in term of landing and discard) and figure 6.6.2.1.1. Catches include the discards of OTB gear, given that discard is not present in artisanal gears. Catches are calculated as sum of landings $a b=$ nd reported discards.

Table 6.6.2.1.1 Red mullet in GSA7. Total landings and discards by country and year.

| Year | FRA- <br> landings | ESP- <br> landings | Total <br> landings | Total <br> discards |  |

## Landings

EWG 19-20 received French and Spanish landings data for GSA 7 by fishing gears, which are listed in table 6.6.2.1.2 and figure 6.6.2.1.2.
Table 6.6.2.1.2 Red mullet in GSA7. Annual landings (t) by gear type, 2004-2018.

Figure 6.6.2.1.2 Red mullet in GSA7. Landings by gear and total landings.

Landings in recent years vary around 300 tons with the maximum in 2016 and the minimum in 2002. The majority of the landings of red mullet are distributed between trawlers ( $>85 \%$ ) and the other part are mainly nets (GNS and GTR). Landings of gears other than OTB, GNS and GTR are on average less than $1 \%$ ).

Length distribution of landings is reported for the Spanish and French OTB fleet from 2004 to 2018 and for the other French gears from 2013 to 2018. Since 2014 to 2018 LFD of the French Trawl fleet are separated by OTB, OTM and OTT trawlers, the majority of catches belonging to OTB but OTT belongs important on the last three years 2016, 2017 and 2018. LFD of this trawl fleets are similar.

For the analyses the LFD of all gears are considered (figure 6.6.2.1.3).

Figure 6.6.2.1.3 Red mullet in GSA7. Landing length distribution from 2004-2018.

## Discards

Discards of red mullet in the GSA 7 are reported for OTB fleets from 2008 to 2018. In 2004-2007 and 2009-2010 the discarded catches were not available. The volume of discards is rather variable among years, around a $3 \%$ as a mean, with some values between $5-8 \%$ (2012-2013). Volume of discard is reported in table 6.6.2.1.4 and in figure 6.6.2.1.4. There are length frequencies distribution of discards from 2012 to 2018 and are reported in figure 6.6.2.1.5.

## Catch at age

For the present assessment, age distribution of red mullet (catches) in GSA 7 has been obtained as sum of landing and discard age distribution estimated using the knife-edge slicing method from the R -script provided during the meeting.

Age data from DCF obtained with a different set of parameters have not been used.
Age distribution by year of the red mullet in GSA 7 is reported in table 6.6.2.1.5 and in figure 6.6.2.1.6.

### 6.6.2.2 EfFORT

The trends in fishing effort by fleet and major gear type targeting red mullet in GSA 7 (OTB, OTM, OTT, GNS and GTR) are listed in tables 6.6.2.2.1 and 6.6.2.2.2 and shown in figures 6.6.2.2.1 and 6.6.2.2.2. Spanish effort values are available from 2004-2017. French effort values are only available from 2015-2017, earlier French data is missing from data call and tables and figures below.

Fishing effort - GTR \& OTB
in GSA 7 -red mullet

Figure 6.6.2.2.2 Red mullet in GSA 7. Trend in fishing days fishing effort for the GTR and OTB fleets, from 2004 to 2017 the increase in 2015 is not a real increase but shows the French data prior to 2015 French data is missing.

### 6.6.2.3 SURVEY DATA

## Methods

According to the MEDITS protocol (Bertrand et al. 2002), trawl surveys were yearly carried out, the majority of them centred in June, applying a random stratified sampling by depth (5 strata with depth limits at: $50,100,200,500$ and 800 m ; each haul position randomly selected in small sub-areas and maintained fixed throughout the time). Haul allocation was proportional to the stratum area. The same gear (GOC 73, by P.Y. Dremière, IFREMER-Sète), with a 20 mm stretched mesh size in the cod-end, was employed throughout the years. Detailed data on the gear characteristics, operational parameters and performance are reported in Dremière and Fiorentini (1996). Considering the small mesh size a complete retention was assumed. All the abundance data (number of fish per surface unit) were standardized to square kilometer, using the swept area method. The period when MEDITS survey has been done in GSA 7 is reported in figure 6.6.2.3.1

Figure 6.6.2.3.1 MEDITS sampling period in GSA 7 .

The number of hauls per MEDITS stratum is shown in Table 6.6.2.3.1.

Table 6.6.2.3.1 Number of hauls per depth stratum in MEDITS trawl survey in GSA 7, A (10-50 $\mathrm{m}), \mathrm{B}(50-100 \mathrm{~m}), \mathrm{C}(100-200 \mathrm{~m}), \mathrm{D}(200-500), \mathrm{E}(500-800 \mathrm{~m}), 1994-2017$.

| 2009 | 11 | 29 | 11 | 6 | 5 | 62 |
| 2010 | 12 | 29 | 9 | 3 | 5 | 58 |
| 2011 | 12 | 31 | 11 | 6 | 5 | 65 |
| 2012 | 12 | 32 | 11 | 5 | 5 | 65 |
| 2013 | 12 | 30 | 11 | 7 | 4 | 64 |
| 2014 | 12 | 31 | 11 | 5 | 6 | 65 |
| 2015 | 12 | 30 | 12 | 5 | 5 | 64 |
| 2016 | 12 | 31 | 11 | 5 | 4 | 63 |
| 2017 | 12 | 32 | 10 | 6 | 5 | 65 |
| 2018 | 12 | 30 | 12 | 6 | 5 | 65 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). The density and biomass indices of red mullet in GSA 7 were estimated on the depth strata to $10-800 \mathrm{~m}$ and standardized to $\mathrm{km}^{2}$.

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in the GSA:

Yst $=\Sigma\left(Y_{i}{ }^{*} A i\right) / A$
$V(Y s t)=\sum\left(A i^{2} * s i^{2} / n i\right) / A^{2}$
Where:
A=total survey area
$A i=a r e a$ of the $i$-th stratum
$\mathrm{si}=$ standard deviation of the i -th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as +/- standard deviation.
It was noted that while this is a standard approach, the calculation may be biased due to a number of different factors including the change in the number of hauls over time, and change of the survey time over the years. Precision may also be affected by the choice of parametric distribution, a normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-Poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. 2004).
Length distributions represented an aggregation (sum) of standardized length frequencies distribution raise to standardized haul abundance per square km over the stations of each stratum.

## Geographical distribution

The geographical distribution pattern of red mullet has been studied in the area using trawlsurvey data and applying geostatistical methods. Abundance and biomass of red mullet in GSA 7 for the year 2017 have shown in the Figure 6.6.2.3.2.

Figure 6.6.2.3.2 Red mullet in GSA 7. 2017 abundance of red mullet in $\mathrm{n} / \mathrm{sqkm}$ on left and biomass of red mullet in $\mathrm{kg} / \mathrm{sqkm}$ at right.

Trends in abundance and biomass
Fishery independent information regarding the state of the red mullet in GSA 7 was derived from the MEDITS survey. Figure 6.6.2.3.3 displays the estimated trend of red mullet abundance and biomass indices standardized to the surface unit in the GSA 7. Indices from MEDITS trawl-surveys show an increasing trend along the series from 2007 to 2016.

Figure 6.6.2.3.3 Red mullet in GSA 7. Abundance ( $\mathrm{n} / \mathrm{sqkm}$ ) on left and biomass ( $\mathrm{kg} / \mathrm{sqkm}$ ) at right, time series of derived from MEDITS (dotted lines indicate standard deviation).

Table 6.6.2.3.2 Red mullet in GSA 7. Stratified abundance indices ( $\mathrm{N} / \mathrm{km}^{2}$ and $\mathrm{kg} / \mathrm{km}^{2}$ ) by year, 1994-2017.

## Trends in abundance by length

The stratified abundance indices of red mullet in GSA 7 from 1994-2018 are given in Figure 6.6.2.3.4. It can be observed some modal peaks in the LFDs in the 2010 and 2016.

Figure 6.6.2.3.4 Red mullet in GSA 7. Stratified abundance indices by size, 1994-2018.

### 6.6.3 STOCK ASSESSMENT

XSA
An assessment has been conducted using XSA method.
The Extended Survivors Analysis (XSA - Darby and Flatman, 1994) has been performed using the same parameters than have been used in the last assessment (GFCM, 2018) in order to compare reference points obtained. XSA has been used with an age range from 0 to +3 and an Fbar 1-2. Discards was included in the analysis so catches are sum of landings and discards. SoP correction was applied.

## Input data

For the assessment of red mullet in GSA 7 the DCF data on the length structure has been used:SOP correction has been applied.. The age distribution has been estimated using the knifeedge slicing method with the fast growth parameters used in the previous assessment. A sexcombined analysis was carried out.

The survey indices from MEDITS data from 2004 to 2018 have been used for the tuning.

Figure 6.6.3.1 Red mullet in GSA 7. Catch (landings + discards) in numbers (thousands) by age and year used in the XSA.

## Results

Several runs of XSA have been performed with the following settings:
Shk.n= TRUE, shk. $\mathrm{f}=$ TRUE, shk. $\mathrm{yrs}=4$, shk.ages=3, rage $=-1$, qage $=2$
Sensitivity analyses have been performed varying the following settings:
Shrinkage of the mean (fse) $=0.5,1,1.5,2$ and 2.5

Figure 6.6.3.3 Red mullet in GSA 7. Plot of the stock parameters estimated in the sensitivity analyses.

The run with catchability (rage) independent on stock size for all ages $=-1$, the catchability (qage) independent of age for ages $>2$ and shrinkage of the mean (fse) $=1.5$ has been chosen on the basis of the residuals and of the retrospective analysis.

Figure 6.6.3.4 Red mullet in GSA 7. Retrospective analysis (2015-2018).

Figure 6.6.3.5 Red mullet in GSA 7. XSA results in terms of recruitment, SSB, Catches and fishing mortality.

The Fbar along the time series is on average 0.96, with a minimum of 0.73 in 2008 and 2017 and a maximum of 1.17 in 2010 and 2016 (Table 6.6.3.4). The recruitment show a stable trend until 2014-2017 period and then increase in 2018.

Table 6.6.3.4 Red mullet in GSA 7. Fishing mortality at age by year, Fbar(0-2), spawning stock biomass (SSB, t) and Recruitment ( $R$, thousands) estimated with XSA.

Figure 6.6.3.6 Red mullet in GSA 7. Fishing mortality at age by year estimated with XSA.

## Method: a4a

A second assessment has been conducted using a4a method, based on linear modelling techniques, all fleets combined, using the same input data as the XSA model.

## Input data

The catch at age matrices, survey MEDITS data and individual weights at age for the stock and for the catch were the same as used on the above XSA assessment and reported in paragraph 6.6.3. The natural mortality vector and the maturity at age are the same reported in paragraph 6.6.1. The a4a model settings were as follows:
fmod $<-\sim s($ age, $k=4)+s($ year, $k=7)$
qmod <- list( $\sim$ factor(replace(age,age>2,2)))
srmodel: ~factor(year)

## Results

The F time series estimated by a4a is shown summarised in Table 6.6.3.7, and as F at age and n at age in Tables 6.6.3.8 and 6.6.3.9. Fishery selection, $F$ at age is shown in Figure 6.6.3.7.
Table 6.6.3.7 Red mullet in GSA 7. Results of the final a4a run: Summary, Recruits, SSB, estimated catch and Fbar (1-2).

Figure 6.6.3.13 Red mullet in GSA 7. Stock results summary. SSB and catches are in tonnes, recruitment in number of individuals (thousand)

Figure 6.6.3.14 Red mullet in GSA 7. Stock results with uncertainty.

Figure 6.6.3.1.5 Red mullet in GSA 7. Stock results a4a vs XSA models.

The a4a asessement is chosen to provide the state of the stock and input stock status for STF below. The a4a assessment has better retrospective performance of $F$ and SSB. The terminal $F$ in XSA is heavily shrunk to the mean giving little information on the last years. A4a also provides
explicit uncertainty analysis. The conclusions are different in detail but both methods concluse $F$ is greater that $\mathrm{F}_{\mathrm{MSy}}$.

### 6.6.4 Reference Points

To define reference points $\mathrm{F}_{01}$ (as a proxy for $\mathrm{F}_{\text {MSY }}$ ) and $\mathrm{F}_{\text {max }}$ a Yield per Recruit analysis (YPR) was carried out in R using FLBRP.

## Input data

As input the same population parameters used for the XSA and a4a and its output of the exploitation pattern for last three years of the assessment.

## Results

The reference points calculated with FLBRP package are shown in table 6.6.4.1.

Table 6.6.4.1 Red mullet in GSA 7. Reference points estimated on the Fbar(-2) using XSA and a4a and for the last assessments (GFCM, 2017, STECF 14-17, 2014). The exploitation status (F/ $\mathrm{F}_{0.1}$ ) is similar for XSA or a4a.

|  | Fo.1 | Fcurrent* | F/F0.1 |
| :--- | :--- | :--- | :--- |
| a4a | 0.62 | 0.82 | 1.32 |
| XSA | 0.52 | 1.2 | 2.3 |
| GFCM 2018 | 0.31 | 0.78 | 2.52 |
| STECF 18-12 - a4a | 0.64 | 1.30 | 2.03 |
| STECF 18-12 - XSA | 0.40 | 0.87 | 2.18 |

*For the present analysis Fcurrent was determined as the FBAR1-2 value for the last year (2018).

Figure 6.6.4.1 Red mullet in GSA 7. Yield per Recruitment, XSA.

### 6.6.5 Short term Forecast and Catch Options

## a4a

Folloing the procedure described in Section 4.3 input parameters used in the XSA and a4a analysis were used for the STF. Different scenarios of constant harvest strategy with $\mathrm{F}_{\text {bar }}$ calculated as the average of ages 1 to 2 and $F$ status quo ( $F_{\text {stq }}=0.82$ based on $F$ in 2018) were performed. Recuitment (class 0) has been estimated from the population results from the geometric mean of the whole series (2004-2018) (61763 thousand) estimated using a4a. The EWG has chosen to use the a4a assessment as this is considered to be more explicitly consistent in its treatment of the data.

Table 6.3.5.2 Red mullet GSA 1: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological <br> Parameters |  | mean weights at age, maturation at age, natural mortality <br> at age and selection at age, based average of 2016-2018 |

*SSB at mid year
Fishing at $F_{0.1}$ (0.62) generates an increase of the catch of $30.7 \%$ from 2018-2020 and a decrease of the spawning stock biomass of $-13.4 \%$ from 2018-2020. Flow and Fupp values are calculated for $\mathrm{F}_{0.1}$, being $\mathrm{F}_{\text {low }}=0.5$ and $\mathrm{F}_{\text {upp }}=1.03$

### 6.6.6 DATA DEFICIENCIES

## Red mullet GSA 7 Effort data

French effort values are only available for the last four years (2015-2018).

### 6.7 NORWAY LOBSTER IN GSA 5

### 6.7.1 Stock Identity and Biology

Due to the lack of information about the structure of the $N$. norvegicus population in the western Mediterranean, this stock was assumed to be confined within the GSA 5 boundaries (Figure 6.9.1.1). Generally managing Norway Lobster is considered to be a local small scale management, as ited to suitable benthic conditions, and occupy specific areas only.

Figure 6.7.1.1. Geographical location of GSA 5.

## Age and growth

For $N$. norvegicus, males and females are known to have different growth profiles, with males growing slower and reaching greater size than females. The DCF data did not include any information on the growth parameters by sex of $N$. norvegicus in GSA 5 . So although the sex ratio in the catches was available in the DCF, growth parameters for both sexes combined were taken used from DCF (see Table 6.8.1.1), there were no previous assessments to compare with practice.

Table 6.8.1.1 parameters used for growth and weight at length taken from DCF data.

| Growth Equation | L $\infty$ | k | $\mathrm{T}_{0}$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{~L}(\mathrm{t})=\mathrm{L}_{\infty} *\left[1-\exp \left(-\mathrm{K}^{*}\left(\mathrm{t}-\mathrm{t}_{0}\right)\right)\right]$ | 86.1 | 0.126 | 0 |
| Weight at Length $^{\text {aL }} \mathrm{a}$ | b |  |  |
| $\mathrm{a}^{\mathrm{b}}$ | 0.000229 | 3.25 |  |

Spawning is considered to occur through the year so spawning time was set at the mid-point of the year with $50 \% \mathrm{~F}$ and M occurring before spawning and a constant of 0.5 was added to t0.

Maturity is taken from DCF data and given in Table 6.8.1.2
Natural mortality is based on growth parameters given above using Chen and Watanabe and given in Table 6.8.1.2.

Table 6.7.1.2 Nephrops in GSA 5: Maturity and Natural mortality parameters used in the assessment

| Age | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Maturity | 0.1 | 0.25 | 0.8 | 1 | 1 | 1 | 1 | 1 | 1 |

| Natural <br> mortality | 0.732 | 0.466 | 0.353 | 0.291 | 0.252 | 0.226 | 0.206 | 0.191 | 0.180 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

### 6.7.2 DATA

### 6.7.2.1 CATCH (LANDINGS AND DISCARDS)

Catch data are available from Spain, for 2002 to 2018, but catch at length is only available from 2009 onwards (Figure 6.9.2.1).

Figure 6.7.2.1 Nephrops in GSA 5: Catch at length by year reported by Spain.
Reported discards at length are low relative to landings and only available since 2009 (table 6.7.2.1, figure 6.7.2.2). Discards have not been included in the total catches because considered negligible.

Figure 6.7.2.2 Nephrops in GSA 5: Catch and landings by year reported by Spain.

Table 6.7.2.1 Nephrops in GSA 5: Total landing discards and total catch by year reported by Spain.

| year | landings | discards | total |
| :--- | :--- | :--- | :--- |
| 2002 | 17.32 | 0 | 17.32 |
| 2003 | 17.77 | 0 | 17.77 |
| 2004 | 25.09 | 0 | 25.09 |
| 2005 | 20.17 | 0 | 20.17 |
| 2006 | 21.27 | 0 | 21.27 |
| 2007 | 57.78 | 0 | 57.78 |
| 2008 | 89.63 | 0 | 89.63 |
| 2009 | 16.34 | 0.05 | 16.39 |
| 2010 | 16.19 | 0 | 16.19 |
| 2011 | 32.26 | 0.07 | 32.33 |
| 2012 | 29.5 | 2.11 | 31.61 |
| 2013 | 18.82 | 0 | 18.82 |
| 2014 | 30.8 | 0.03 | 30.83 |
| 2015 | 72.87 | 0.74 | 73.61 |
| 2016 | 28.33 | 0.02 | 28.35 |

| year | landings | discards | total |
| :--- | :--- | :--- | :--- |
| 2017 | 57.82 | 0.02 | 57.84 |
| 2018 | 82.91 | 0 | 82.91 |

Reported catches at length were raised to the total by using the sum of products correction. SOP corrections were high, similar in all years but higher than expected between 1.65 in 2018 compared to 1.11 in 2017 (Figure 6.7.2.3).

Figure 6.7.2.3 Nephrops in GSA 5: Total landing by year reported by Spain and factor needs for SOP correction.

Table 6.7.2.2 Nephrops in GSA 5: SOP corrections for years applied to raised catch at length/age used in the assessment.

| 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 | 2016 | 2017 | 2018 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1.45 | 1.21 | 1.22 | 1.19 | 1.26 | 1.21 | 1.12 | 1.38 | 1.11 | 1.65 |

Catch at length was deterministically length sliced to numbers and mean weights at age for the assessment using the growth parameters and weight length relationship given in Table 6.9.1.1. but 0.5 was added to t0 due to the spawing season of the species that occur in the middle of the year. The original parameters were taken from the DCF data call and considered reasonable.

Figure 6.7.2.2 Nephrops in GSA 5: Catch at age by year from length sliced catch at length.

In conclusion catch at age is available from 2009 to 2017, in addition total catch is available for earlier years 2002 to 2008, but without length or age data.

### 6.7.2.2 EfFORT

In GSA 5 catches Norway lobster are only reported by trawl vessels (OTB).
Available information about OTB effort in GSA 5 shows a decreasing trend in the last 10 years (Figure 6.7.2.2.1).

Figure 6.7.2.2.1 Nephrops in GSA 5: Days at sea by OTB fleet and by year.

### 6.7.2.3 SURVEY DATA

The MEDITS survey was conducted in a restricted way from 1995 to 2006. In, in 2007 the number of stations was increased greatly (Figure 6.9.2.3) and MEDITS was conducted consistently from 2007 to the present. The early data with very few hails per year was not considered suitable for a tuning index, given also that during most of that period only total catch would be available.

The mean depth of occurrence of the specie is $492 \pm 152 \mathrm{~m}$, and the species occur below

Figure 6.7.2.3, number of MEDITS hauls per year 1995 to 2017, (increase in 2007).

Observed abundance and biomass indices of Norway lobster and the length frequency distributions are given in the figures below for GSA5. Both estimated abundance and biomass indices show a similar high variable pattern throughout the time series trends, with a sharp increase of density in the last year (Figure 6.7.2.3).

Figure 6.7.2.3. Norway lobster GSA 5. Estimated biomass indices (kg/km²) and abundance indices ( $\mathrm{N} / \mathrm{km}^{2}$ ) in whole time series.

In the last ten years the pattern is less variable with a greater uncertainity during the peaks (Figure 6.7.2.4).

Figure 6.7.2.4. Norway lobster GSA 5. Comparison of biomass indices ( $\mathrm{kg} / \mathrm{km}^{2}$ ) and abundance indices ( $\mathrm{N} / \mathrm{km}^{2}$ ) in the last 10 years (density are shifted slightly on year axis to avoid overlapping).

Standardized MEDITS catch at length data (Figure 6.7.2.5) was length sliced to give catch at age Figure (6.7.2.6) using the same growth and length parameters as the catch (Table 6.7.1.1).

Figure 6.7.2.4. Nephrops in GSA 5: MEDITS catch at length by year

Figure 6.7.2.5. Nephrops in GSA 5: MEDITS mean catch/rate at age by year derived from length by slicing.

The conclusion to the data investigation, is that only age disaggregated data is available from 2007 for the survey and 2009 for the catch, the best option for the assessment is when both catch and index are available age disaggregated. So the assessment is run based on catches from 2009 to 2018. The addition of just two extra years 2007 and 2008 with no age data for catch was considered to increase model complexity without any real benefits in information.

### 6.7.3 STOCK ASSESSMENT

Stock assessment input data is given in Tables 6.7.3.1 to 6.7.3.4
Table 6.7.3.1 Nephrops in GSA 5: Total Catch by year in tonnes

| Age | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 | 2016 | 2017 | 2018 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| All | 16.34 | 16.19 | 32.26 | 29.50 | 18.82 | 30.80 | 72.87 | 28.35 | 57.82 | 82.91 |

| 9 | 1.139 | 0.594 | 0.346 | 1.356 | 2.260 | 1.649 | 0.915 | 1.337 | 1.381 | 0.512 |

The stock assessment was explore for two final models. In particular two separable f models were used:

```
fmodel0 <- ~ factor(age) + factor(year)
fmodel1 <- ~factor(replace(age,age>6,6)) + s(year,k=4)
```

while the same catchability and stock recruitment models were considered

```
qmodel1 <- ~factor(replace(age,age>5,5))
srmodel0 <- ~ factor(year)
```

Assessment results of Nephrops in GSA 5 are given in tables 6.7.3.6 to 6.7.3.8 and figure 6.7.3.1.

Table 6.7.3.8 Nephrops in GSA 5: Stock assessment summary table by year in the two models, Fishing morality, Recruitment (thousands) Spawing stock biomass (tonnes) and catch (tonnes)

| Fit | year | Fbar | Recruitment | SSB | TB | Catch |
| ---: | :--- | :--- | ---: | ---: | ---: | ---: |
| 1 | 2009 | 0.22 | 3110 | 52 | 83 | 15 |
| 1 | 2010 | 0.19 | 3138 | 67 | 102 | 17 |
| 1 | 2011 | 0.33 | 2670 | 74 | 120 | 34 |
| 1 | 2012 | 0.24 | 3639 | 77 | 121 | 26 |
| 1 | 2013 | 0.15 | 4267 | 94 | 142 | 20 |
| 1 | 2014 | 0.2 | 4063 | 111 | 168 | 32 |
| 1 | 2015 | 0.46 | 4208 | 104 | 187 | 71 |
| 1 | 2016 | 0.2 | 3678 | 102 | 154 | 29 |
| 1 | 2017 | 0.39 | 6263 | 103 | 185 | 59 |
| 1 | 2018 | 0.69 | 14914 | 92 | 223 | 77 |

| fit | year | Fbar | Recruitment | SSB | TB | Catch |
| ---: | :--- | :--- | ---: | ---: | ---: | ---: |
| 2 | 2009 | 0.23 | 2946 | 54 | 84 | 15 |
| 2 | 2010 | 0.25 | 2929 | 65 | 101 | 21 |
| 2 | 2011 | 0.27 | 2607 | 73 | 113 | 26 |
| 2 | 2012 | 0.28 | 3020 | 77 | 119 | 28 |
| 2 | 2013 | 0.27 | 3689 | 83 | 132 | 29 |
| 2 | 2014 | 0.27 | 3612 | 89 | 139 | 31 |
| 2 | 2015 | 0.28 | 4035 | 95 | 152 | 35 |
| 2 | 2016 | 0.34 | 3780 | 97 | 157 | 43 |
| 2 | 2017 | 0.44 | 6805 | 93 | 172 | 53 |
| 2 | 2018 | 0.62 | 16535 | 95 | 223 | 63 |

Cohorts consistence was checked for both landings and survey index (Figure 6.7.3.1). Consistence among cohorts was poor both in survey index and catches.

NEP GSA5 - tuning

NEP GSA5 - catches

$\log _{10}$ (Index Value)

Figure 6.7.3.1. Norway lobster GSA5; cohorts consistence in catch (right panel) and tuning index (left panel).

The assessment models diagnostics are shown in Figures 6.7.3.1, 6.7.3.2 and 6.7.3.3. Generally the residuals are moderate, with some year effects visible in both catch and survey indices, particularly in Fit 2. Catch and index observations and estimates given in Figures 6.7.3.2 and 6.7.3.3 are similar without major outliers in both data sets.

Figure 6.7.3.1 Nephrops in GSA 5: Normalised log residuals for catch and abundance indices in the two models.

Figure 6.7.3.2 Nephrops in GSA 5: Observations and estimated catch at age and year in the two model ( $A=$ Fit1, $B=$ Fit2).

Figure 6.7.3.3 Nephrops in GSA 5: Observations and estimated MEDITS index at age and year in the two model ( $\mathrm{A}=$ Fit1, $\mathrm{B}=\mathrm{Fit2}$ ).

Fishing mortality

Figure 6.7.3.4 Nephrops in GSA 5: Fishing mortality at age and year in the two models.

Figure 6.7.3.5 Nephrops in GSA 5: Selection pattern for MEDITS index at age and year (flat age 5 and above) in the two models.

Figure 6.7.3.6 Nephrops in GSA 5: Stock summary 2009 to 2017, Recruitment, SSB, catch and Fishing mortality in the two models.

Figure 6.7.3.7 Nephrops in GSA 5: Analytical retrospective 2009 to 2017, in the two model ( $A=$ Fit1, $B=$ Fit2), Recruitment, SSB, catch and Fishing mortality.

Figure 6.7.3.8 Nephrops in GSA 5: Stock summary and 90\% intervals 2009 to 2018 in the two models (Recruitment, SSB, catch and Fishing mortality).

Some aspects of the assessment look good, for example the log residuals for catch and abundance indices, but neither Fit1 nor Fit2 show a stable retrospective performance. Both catch and tuning data are lacking of coherent information comparing cohorts across years.

EWG 19-10 concluded that the output of the a4a models were both not suitable to provide the basis of the current status of the stock but could be used as indicative of a trend. The survey index appears reasonably coherent so the use of that index is considered likely to give an indications of the state of the stock. Based on this, advice was given using the ICES category 3 index method see Section 6.9.5 below.

### 6.7.4 Reference Points

As the assessment was not accepted for advice, reference points are not calculated.

### 6.7.5 Short term Forecast and Catch Options

Biomass Index refers to the ICES data limited approach using a stock status indicator (ICES 2012). In the last years biomass of norway lobster in GSA 5 has displayed a stable/sligthly decreasing trend (figure 6.9.5.1). The change in biomass over the last five years was used to provide an index for change (0.98). As the biomass index change is lower than 1.2 and greater than 0.8 , following the ICES approach, STECF EWG 19-10 used the index of change and a precautionary buffer value of 0.80 to multiply the catch (mean catch over 2016-2018). The catch advice, which is applicable for two years (2019 and 2020) is 44.1 tonnes (Table 6.9.5.1).
Table 6.7.5.1: Assumptions made for the interim year and in the forecast

| Index A (2017-2018) |  | 2.70 |
| :---: | :---: | :---: |
| Index B (2014-2016) |  | 2.75 |
| Index ratio (A/B) |  | 0.98 |
| -20\% Uncertainty cap | Not applied |  |
| Average catch (2016-2018) |  | 56.35 |
| Discard rate (2016-2018) |  | 0 (negligible) |
| -20\% Precautionary buffer | Applied |  |
| Catch advice ** |  | 44.1 |
| Landings advice *** |  | 44.1 |
| \% advice change ^ |  | -47\% |

Figure 6.7.5.1 Norway lobster GSA 5. Biomass index (kg/km2) estimated from MEDITS survey. In green the mean of the last two years (2.70) compared to the previous three years in blue (2.75).

### 6.7.6 DATA DEFICIENCIES

The analysis of MEDITS data, showed a problem in the size distribution of Nep in 2013 with two anomalous peaks. A deeper check of row data showed wrong nbtot reported number (350) for the haul coded 150.

### 6.8 NORWAY LOBSTER IN GSA 6

### 6.8.1 STOCK IDENTITY AND BIOLOGY

Due to the lack of information about the structure of the $N$. norvegicus population in the western Mediterranean, this stock was assumed to be confined within the GSA 6 boundaries (Figure 6.8.1.1). Generally, managing Norway Lobster is considered to be suited to local small scale management issue, as stocks are linked to suitable benthic conditions, and occupy specific areas only.

Figure 6.8.1.1. Geographical location of GSA 6.

Age and growth
For $N$. norvegicus, males and females are known to have different growth profiles, with males growing slower and reaching greater size than females. The DCF data did not include any information on the growth parameters of $N$. norvegicus in GSA 6. For this reason, the same parameters of the last assessment, from DCF for GSA 5 (see Table 6.8.1.1) were used again.

Table 6.8.1.1. Norway lobster in GSA 6: Parameters used for growth and weight at length.

| Growth Equation | $\mathbf{L}_{\infty}$ | $\mathbf{k}$ | $\mathbf{t o}_{\mathbf{0}}$ |
| :---: | :---: | :---: | :---: |
| $\mathbf{L}(\mathbf{t})=\mathbf{L}_{\infty} *\left[\mathbf{1}-\exp \left(-\mathbf{K}^{*}\left(\mathbf{t}-\mathbf{t}_{\mathbf{0}}\right)\right)\right]$ | 86.1 | 0.126 | 0 |
| Weight at Length | $\mathbf{a}$ | $\mathbf{b}$ |  |
| $\mathbf{a L}^{\mathbf{b}}$ | 0.000229 | 3.25 |  |

Spawning is considered to occur through the year so spawning time was set at the mid-point of the year with $50 \% \mathrm{~F}$ and M occurring before spawning.

As agreed by EWG19-10, length data from catches and MEDITS survey were age sliced using the standard length slicing software (L2a) by adding 0.5 to $\mathrm{t}_{0}$ for internal consistency in the stock assessment model.

Maturity and natural mortality were taken from the previous assessment (Table 6.8.2).

Table 6.8.1.2. Norway lobster in GSA 6: Maturity and Natural mortality parameters used in the assessment

| Age | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Maturity | 0.1 | 0.25 | 0.8 | 1.0 | 1.0 | 1.0 | 1.0 |
| Natural mortality | 0.732 | 0.466 | 0.353 | 0.291 | 0.252 | 0.226 | 0.206 |

### 6.8.2 Data

All data were taken from 2019 DCF data call.

### 6.8.2.1 CATCH (LANDINGS AND discards)

Catch data are available from GSA 6, since 2002. Reported discards are low relative to landings (Figure 6.8.2.1, Table 6.8.2.1).

Figure 6.8.2.1. Norway lobster in GSA 6: Total landing discards and total catch by year reported by Spain.

Table 6.8.2.1. Norway lobster in GSA 6: Total landing discards and total catch by year reported by Spain.

|  | landings | discards | total |
| :---: | :---: | :---: | :---: |
| 2002 | 187.5 | 0 | 187.5 |
| 2003 | 381.81 | 0 | 381.81 |
| 2004 | 321.72 | 0 | 321.72 |
| 2005 | 351.99 | 0 | 351.99 |
| 2006 | 390.18 | 0 | 390.18 |
| 2007 | 409.4 | 0 | 409.4 |
| 2008 | 393.77 | 0 | 393.77 |
| 2009 | 355.6 | 0.01 | 355.61 |
| 2010 | 406.45 | 0.06 | 406.51 |
| 2011 | 496.84 | 11.37 | 508.21 |
| 2012 | 506.09 | 65.8 | 571.89 |
| 2013 | 478.36 | 12.34 | 490.7 |
| 2014 | 489.95 | 10.84 | 500.79 |
| 2015 | 355.24 | 6.34 | 361.58 |
| 2016 | 308.06 | 6.41 | 314.47 |
| 2017 | 282.22 | 11.02 | 293.24 |
| 2018 | 287.03 | 0 | 287.03 |

Information at length is available from 2009 onwards (Figure 6.8.2.2).

Figure 6.8.2.2. Norway lobster in GSA 6: Total catch by lengths and year reported by Spain for GSA 6.

Discards have been included in the total catches and the catches at length raised to the total with the sum of products correction. SOP corrections were similar in all years (Table 6.8.2.2).

Table 6.8.2.2. Norway lobster in GSA 6: SOP corrections for years applied to raised catch at length/age used in the assessment.

| year | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 | 2016 | 2017 | 2018 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| SOP | 1.34 | 1.21 | 1.52 | 1.63 | 1.40 | 1.40 | 1.39 | 1.47 | 1.51 | 1.39 |

### 6.8.2.2 EFFORT

Fishing effort data were reported to STECF EWG 19-10 through DCF. Nominal effort by fleet that report catches of some norway lobster in GSA 6, is almost exclusively related to bottom trawl gears (Table 6.8.2.2.1 and figure 6.8.2.2.2). Catches by other gears are negligible

Figure 6.8.2.2.1 Norway lobster in GSA 6: Fishing days by OTB and year.

### 6.8.2.3 SURVEY DATA

Since 1994, MEDITS trawl surveys has been carried out each year during the spring season in GSA 6 (Figure 6.8.2.3.1).

Figure 6.8.2.3.1. Medits survey periods (1994-2018) in GSA 6.

Length frequency distributions and observed abundance and biomass indices of Norway lobster in GSA 6 are given in the figures below (Figures 6.8.2.3.2-4). Both estimated abundance and biomass indices show similar trends, with a slight increase in the last year (2018). MEDITS numbers at length data were length sliced to give catch at age matrix (Figure 6.8.2.3.5).

Figure 6.8.2.3.2. Norway lobster in GSA 6: length frequency distribution by year of MEDITS. (sampling in 2006 was by 5 mm giving fewer higher values, and at 1 mm in all other years)

### 6.8.3 STOCK ASSESSMENT

The statistical catch-at-age method Assessment for All (a4a) (Jardim et al., 2015) was used to estimate historical population size.
Using the 12 a routine in FLR, catch at length was deterministically length sliced to obtain numbers and mean weights at age for the assessment using the growth parameters and weight length relationship given in Table 6.8.1.1. (figures 6.8.3.1-2).

Figure 6.8.3.1. Norway lobster in GSA 6: Proportion at age by year from length sliced catch at length (a) and index at length (b).

Figure 6.8.3.2. Norway lobster in GSA 6: Catch at age by year from length sliced catch at length.

## Input data

Stock assessment input data for the a4a model are given in Tables 6.8.3.1 to 6.8.3.5.

Table 6.8.3.1. Norway lobster in GSA 6: Total Catch by year in tonnes.

## Assessment results (method a4a)

The stock assessment was based on the following submodels:

```
fmodel: ~factor(age) + factor(year)
srmodel: ~s(year, k = 4)
qmodel: ~factor(replace(age, age > 5, 5))
```

Norway lobster in GSA 6: Assessment results are shown in Figures 6.8.3.3 to 6.10.3.3.10 and given in Table 6.8.3.6 to 6.8.3.8.

Figure 6.8.3.3. Results of the best a4a model for norway lobster in GSA 6.

Figure 6.8.3.10. Norway lobster in GSA 6. Internal consistency of the catch at age data

Figure 6.8.3.11. Norway lobster in GSA 6. Internal consistency of the MEDITS index at age data Retrospective
The retrospective analysis applied up to 3 years back shows quite moderate stability for the models (Figure 6.8.3.12), however, the conclusions on stock exploitation status of $\mathrm{F}>\mathrm{F}_{0.1}$ is maintained throughtout.

Figure 6.8.3.12. Norway lobster in GSA 6: Analytical retrospective 2009 to 2018, Recruitment, SSB, catch and Fishing mortality.

Figure 6.8.3.13. Norway lobster in GSA 6: Stock summary (Recruitment, SSB, catch and Fishing mortality) and 90\% confidence intervals 2009 to 2018.

## Conclusions to the assessment

This assessment is considered acceptable, the age sliced catch data has coherence from year to year and the assessment provides a coherent explanation of the trend in catches. Retrospective performance is moderate and confirms stock explitation status at F well above FMSY throughout.
Based on the a4a results, the Norway lobster in GSA 6 shows SSB and recruits with a decreasing trend since 2016 and a very slight increase from 2017. Fbar (3-6) fluctuated and shows a decreasing trend in the last years down to a value of 0.63 in 2018.
In conclusion, the biomass status for the Norway lobster in GSA 6 appears low and stable.

### 6.8.4 Reference Points

Based on input data the reference points are given in Table 6.8.4.1.

| refpt | harvest | yield | rec | ssb | biomass |
| :---: | :---: | :---: | :---: | :---: | :---: |
| virgin | 0.000 | 0 | 1 | 0.1617 | 0.166 |
| msy | 0.198 | 0.010 | 1 | 0.0431 | 0.047 |
| crash | 1030.000 | 0.005 | 1 | 0.00000000008 | 0.000 |
| Fo.1 | 0.113 | 0.0096 | 1 | 0.0672 | 0.071 |
| fmax | 0.198 | 0.010 | 1 | 0.0431 | 0.047 |
| spr.30 | 0.173 | 0.010 | 1 | 0.0486 | 0.052 |

### 6.8.5 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the NEP GSA 6 stock assessment.
For mean weights, maturity, natural mortality and selection pattern, an average of the last three years was used. Recruitment is observedto be quite stable over the examined period, so recruitment for 2019 to 2021 has been estimated from the population results as the geometric mean of the whole time series (51814). The averaged $F_{b a r}=0.71$ (2016-2018) from the a4a assessment was used for $F$ in 2019.

Table 6.8.5.1 Norway lobster in GSA 6: Assumptions made for the interim year and in the forecast.

| Variable | Value |  |
| :--- | :---: | :--- |
| Biological <br> Parameters |  | average of 2016-2018 |
| Fages 3-6 (2019) | 0.71 | mean F 2016-18 used to give F status quo for 2019 |
| SSB (2019) | 494.24 | Stock assessment 1 January 2019 |
| Rage0 (2019,2020) | 51813.89 | Geometric mean of the last 10 years |
| Total catch (2019) | 347.12 | Assuming F status quo for 2019 |

*SSB at mid year

### 6.8.6 DATA DEFICIENCIES

A lack of growth parameters and length weight relationship coefficient has been detected. As previously observed, the length distribution in 2001 is very different from all the other years and reported for greater bins than usual.

### 6.9 HAKE IN GSA 9, 10 AND 11

### 6.9.1 Stock Identity and Biology

The assessment of European hake carried out during the STECF EWG 19-10 considered the stock shared by the GSAs 9, 10 and 11 .

Figure 6.9.1.1. Geographical location of GSAs 9, 10 and 11.

Growth parameters and length-weight parameters were those used for the previous assessment (STECF EWG 18-12), as provided through the DCF data calls by each GSA. In GSAs 9 and 10, VBGF curves by sex were available from the beginning of the time series, while in GSA 11 a sexcombined growth curve was provided for the whole time series. The von Bertalanffy growth curves did not change significantly among the three sets of parameters available (Figure 6.9.1.2). To obtain sex specific growth in GSA 11, the parameters of GSA 9 were applied to the data from GSA 11. The VBGF and LW relationship parameters used are summarized in the following table (Tab. 6.9.1.1).

Figure 6.9.1.2. European hake in GSAs 9, 10 and 11. Von Bertalanffy growth curves provided within the DCF; red line for females in GSA 9, blue line for males in GSA 9, orange line for females in GSA 10, green line for males in GSA 10, black line for sex combined in GSA 11.

Table 6.9.1.1. European hake in GSAs 9, 10 and 11. Growth parameters and length-weight relationship parameters used in the assessment.

| GSA | Sex | Linf | $\mathbf{k}$ | $\mathbf{t 0}$ | $\mathbf{a}$ | $\mathbf{b}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{2} \mathbf{9}$ | M | 54.78 | 0.22 | -0.3 | 0.007 | 3.027 |
|  | F | 87.18 | 0.15 | -0.27 | 0.006 | 3.066 |
| $\mathbf{2} \mathbf{1 0}$ | M | 73 | 0.13 | -0.82 | 0.004 | 3.166 |
|  | F | 111 | 0.1 | -0.59 | 0.004 | 3.191 |
| $\mathbf{1} \mathbf{1 1}$ | M | 54.78 | 0.22 | -0.3 | 0.007 | 3.027 |
|  | F | 87.18 | 0.15 | -0.27 | 0.006 | 3.066 |

The maturity and natural mortality vector used were the same as in the previous assessment (Tables 6.9.1.2 and 6.9.1.3).

Table 6.9.1.2. European hake in GSAs 9, 10 and 11. Maturity vectors used in the assessment.

| Maturity | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6 +}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| GSA 9 | 0.01 | 0.11 | 0.58 | 0.94 | 1 | 1 | 1 |
| GSA 10 | 0.00 | 0.03 | 0.34 | 0.92 | 0.99 | 1 | 1 |
| GSA 11 | 0.00 | 0.00 | 0.19 | 0.85 | 1 | 1 | 1 |

Table 6.9.1.3. European hake in GSAs 9, 10 and 11. Natural mortality vectors used in the assessment.

### 6.9.2 DATA

### 6.9.2.1 CATCH (LANDINGS AND DISCARDS)

European hake is one of the main target species in terms of landings, incomes and vessel involved in the area. In GSAs 9 and 10, it is mainly exploited by trawlers on the shelf and slope, but also by small-scale fisheries using set nets (gillnets and trammel nets) and bottom long-lines. In GSA 11, although hake is not target of a specific fishery, it is one of the most important species in terms of biomass landed. It is caught exclusively by a mixed bottom trawl fishery that operates at depth between 50 and 800 m . No gillnet or longline fleets target this species, but it can be find as by catch of gillnet fleets targeting other species.

## Landings

Landings data were reported to STECF EWG 19-10 through the DCF. In GSAs 9, 10 and 11, most of the landings come from otter trawls. The contribution of set nets to the total landing is around the $35 \%$ in GSAs 9 and 10; longlines in GSA 10 contribute for around the $17 \%$ to the total landing. In GSA 11 landing data come exclusively from the bottom trawl fishery. Landings data by
year and fleet are presented in Figure 6.9.2.1.1, total landings by year are presented in Table 6.9.2.1.1.

HKE_ITA_9_TOTAL_LANDING

Figure 6.9.2.1.1. European hake in GSAs 9, 10 and 11. Landings data in tons by year and fleet.
Table 6.9.2.1.1. European hake in GSAs 9, 10 and 11. Landings data in tons by year and GSA.

|  | Total Landing (tons) |  |  |  |

| $\mathbf{2 0 1 8}$ | 605 |  |  |  |

Length frequency distribution of the landings by year and fleet from the DCF database are presented in Figure 6.9.2.1.2.

(2) Length (cm)

Figure 6.9.2.1.2. European hake in GSAs 9, 10 and 11. Length frequency distribution of the landings by year and fleet.

## Discards

Discards data were reported to STECF EWG 19-10 through the DCF, and they were included in the stock assessment. For the years in which discards data were missing, they were estimated on the basis of the discard ratio (discard/landing) of the available years and the landing time series. The highest discard rate were represented by the bottom trawl fishery; for the other gears the discards were negligible. Total discard by year for the bottom trawl fishery is presented in Table 6.9.2.1.2.
ble 6.9.2.1.2. European hake in GSAs 9,10 and 11 . OTB discards data in tons by GSA.

### 6.9.2.3 SURVEY DATA

The MEDITS (MEDiterranean International Trawl Survey) survey is an extensive trawl survey occurring in all European countries and included in the Data Collection Framework. According to the MEDITS protocol (Bertrand et al., 2002), it takes places every year during springtime, following a random stratified sampling by depth (5 strata: 0-50 m, 50-100 m, 100-200 m, 200500 m and over 500 m ). The number of hauls in each stratum is proportional to the surface of the stratum and their positions were randomly selected and maintained fixed throughout the time. Same sampling gear (GOC73), characterized by a 20 mm stretched mesh size cod-end, is used throughout GSAs and years.
In the current assessment, combined MEDITS data for GSAs 9, 10 and 11 from 2005 onwards were used, as commercial data were available for the three GSAs starting from that year.
The combined MEDITS indexes were calculated using the script provided by JRC (Figures 6.9.2.3.1 and 6.9.2.3.2).

Figure 6.9.2.3.1. European hake in GSAs 9, 10 and 11. Estimated biomass indices from the MEDITS survey ( $\mathrm{kg} / \mathrm{km}^{2}$ ).

Figure 6.9.2.3.2. European hake in GSAs 9, 10 and 11. Estimated density indices from the MEDITS survey ( $\mathrm{n} / \mathrm{km}^{2}$ ).

Both estimated abundance and biomass indices show similar trends, with strong fluctuations throughout the time series.
Size structure indices are shown in Figure 6.9.2.3.3.

### 6.9.3 STOCK ASSESSMENT

A statistical catch-at-age assessment was carried out for this stock, using the Assessment for All Initiative (a4a) method (Jardim et al., 2015). The a4a method utilizes catch-at-age data to derive estimates of historical population size and fishing mortality. However, unlike XSA, model parameters estimated using catch-at-age analysis are done so by working forward in time and analyses do not require the assumption that removals from the fishery are known without error. The assessment was carried out using the period 2005-2018 for catch data and tuning file. Both catch numbers at length and index number at length were sliced using the a4a age slicing routine in FLR, using for each GSA the corresponding growth parameters by sex. The analyses were carried out for the ages 0 to $6+$. Concerning the Fbar, the age range used was 1-3 age groups.

## Input data

The growth parameters used for VBGF were the one reported in table 6.9.1.1.
Total catches and catch numbers at age from the single GSAs were used as input data. SOP correction was applied to catch numbers at age (Table 6.9.3.1).

Table 6.9.3.1. European hake in GSAs 9, 10 and 11. SOP correction vector by GSA.

## Assessment results

Different a4a models were performed (combination of different $f$ and $q$ ). The best model (according to residuals and retrospective) included:
$\mathrm{f} \sim \mathrm{s}($ age, $\mathrm{k}=3)+\mathrm{s}($ year, $\mathrm{k}=8)+\mathrm{s}($ year, $\mathrm{k}=8$, by=as.numeric $($ age $==0)$ )
$\mathrm{q} \sim \operatorname{list}(\sim$ factor(age))

Results are shown in Figures 6.9.3.3-6.9.3.9.

Figure 6.9.3.3. European hake in GSAs 9, 10 and 11. Stock summary from the final a4a model.

Based on the a4a results, the European hake SSB shows a decreasing trend from the beginning of the time series, from a maximum of 7746 tons in 2006 to minimum of 3576 tons in 2018. The assessment shows a decreasing trend in the number of recruits in the time series. The recruitment (age 0) reached a minimum of 117106 thousands individuals in 2017, followed by a slight increase up to 165298 thousands individuals in 2018. Far (1-3) shows a fluctuating pattern with a slightly increasing trend in the time series, with a value of 0.80 reached in 2018. The retrospecive performance is moderate, but shows that the $F$ is high, well above $\mathrm{F}_{\text {msy }}$ over the whole time series.

### 6.9.4 Reference Points

The time series is too short to give stock recruitment rationship, so reference points are based on equilibrium methods. The STECF EWG $19-10$ recommended to use $\mathrm{F}_{0.1}$ as proxy of Fmsy. The library FLBRP available in FLR was used to estimate $F_{0.1}$ from the stock object resulting from the outputs of the a4a assessment.
Current $F$ ( 0.80 , estimated as the $F_{b a r 1-3}$ in the last year of the time series, 2018) is higher than $F_{0.1}(0.22)$, chosen as proxy of $\mathrm{F}_{\mathrm{MSy}}$ and as the exploitation reference point consistent with high long-term yields, which indicates that European hake stock in GSAs 9, 10 and 11 is overexploited.

### 6.9.5 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the a4a stock assessment. The choice of parameter values used followed the procedure described in Section 4.3. An average of the last three years has been used for weight at age, maturity at age and Fbar.

Recruitment shows a fluctuating pattern over the period of the assessment, so it has been estimated from the population results as the geometric mean of the last whole time series years (180785 thousands).

### 6.9.6 Data Deficiencies

GSA10: unlikely length measures (total length more than 100 cm ) were found for European hake (HKE) in MEDITS data in 2017. Regarding commercial data, LFDs and relative landings are missing for 2017 third quarter and 2018 first one. LFDs in 2018 are reported with a 2 cm step. No discard data are available for 2018. Very low discard values in 2017, compared to the previous years time series.
MEDITS data provided for hake in GSA11 present some issues in the TC file, maybe due to uncorrect raising procedures. In 2006, for example, haul 71 presents a raising factor of 885 only for size 395; in 2008, haul 30 presents a raising factor of 391 for lengths 280, 300, 310 and 420. This results in biased LFD patterns.

### 6.10 DEEP-WATER ROSE SHRIMP IN GSA 9, 10 \& 11

### 6.10.1 Stock Identity and Biology

According to the results of Stockmed project (Fiorentino et al., 2014), Deep-water rose shrimp of GSA09 is part of the stock that includes many GSAs of western Mediterranean (GSA01, GSAs 0508, GSA11). However, the analyses underlined that the southern part of GSA09 presents characteristics more similar to those of GSA10. In the present assessment, the stock was assumed to be confined within the GSAs 09, 10 and 11 boundaries.

Figure 6.10.1.1 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Geographical location of the GSAs.

The Deep-water rose shrimp is an epibenthic species and inhabits the muddy or sandy-muddy bottoms of the continental shelf. A gradient of size increasing with depth has been observed in the area, being the smallest specimens fished more frequently in the upper part of the continental shelf (100-200 m), while the largest ones are mainly distributed along the slope at depths greater than 200 m (, Ardizzone et al., 1990; Spedicato et al., 1996).

In GSA09, the species shows a wide bathymetric distribution, being present from 50 to 650 m depth with greatest abundance between 150 and 400 m depth over muddy or sandy-muddy bottoms (Ardizzone and Corsi, 1997; Biagi et al., 2002). The highest abundances have been found in the Tyrrhenian part of the GSA (south Tuscany and Latium). In GSA10, aggregations with higher abundance were localised between 100 and 200 m depth, with some intrusions in the deeper waters in three sub-areas. Two most important patches were located in the Gulf of Naples and along the Calabrian coasts in correspondence with Cape Bonifati, while a third one in the Gulf of Salerno (Lembo et al., 1999). These are the areas where also the main nurseries are localised (Lembo et al., 2000a).

The Deep-water rose shrimp with hake and red mullet is a key species of fishing assemblages in the area. In the last decade it was generally also ranked among the species with higher abundance indices (number of individuals) in the trawl surveys (e.g. Spedicato et al, 2003) as observed for different Mediterranean areas (Abelló et al., 2002). The species is caught on the same fishing grounds as European hake and the production of this shrimp is steadily growing in
the last decade in the southern basin and it reached in 2006 about $10 \%$ of the demersal landings. The core of nursery areas in GSA09 overlap with crinoid beds (Leptometra phalangium) areas over the shelf-break (Colloca et al., 2004, 2006a; Reale et al., 2005). This is a peculiar habitat in the GSA09, which is also an essential fish habitat for other commercially important species as the European hake, Merluccius merluccius.

## Growth

The structure of the sizes of $P$. longirostris is characterised by differences in growth between the sexes, the larger individuals being females. The Deep-water rose shrimp is a short-living crustacean with a life span of about 4 years (Carbonara et al., 1998).

The growth of $P$. longirostris has been studied in the southern part of the GSA09 (central Tyrrhenian Sea) using modal progression analysis (Ardizzone et al., 1990). The following sets of Von Bertalanffy growth parameters were estimated: Females: $\mathrm{L} \infty=43.5, \mathrm{~K}=0.74, \mathrm{t} 0=-0.13$; Males: $\mathrm{L} \infty=33.1, \mathrm{~K}=0.93, \mathrm{t} 0=-0.05$. Females grow faster than males attaining larger size-atage.

In GSA10, past estimates of the growth pattern of the Deep-water rose shrimp females were obtained using different methods based on the LFD analysis (modal progression analysis-MPA, Elefan, Multifan) applied to GRUND data from 1990 to 1995. Parameters of VBGF were as follows: L $\infty=45.9 ; \mathrm{K}=0.673 \mathrm{t0}=-0.251$ (Carbonara et al., 1998). VBGF parameters were also re-estimated during the Samed project (SAMED, 2002) using the MEDITS time series from 1994 to 1999, that gave the following values: females: $\mathrm{CL} \infty=45.0 \mathrm{~mm}, \mathrm{~K}=0.7$, $\mathrm{t} 0=-0.15$; males: $\mathrm{CL} \infty=40.0 \mathrm{~mm}$; $\mathrm{K}=0.78$; $\mathrm{t} 0=-0.2$.

Figure 6.10.1.2 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Von Bertalanffy curves.

For the present assessment the growth parameters reported in Tab. 6.10.1.1 has been used. Weight length relationships for the different years and GSAs have been obtained from DCF database.

Table 6.10.1.1 Deep-water rose shrimp in GSAs 09, 10 \& 11. Growth parameters used in the present assessment.

| $\mathbf{0 9}$ | Females | 43.5 | 0.74 | -0.13 |
| :---: | :---: | :---: | :---: | :---: |
| $\mathbf{0 9}$ | Males | 33.1 | 0.93 | -0.05 |
| $\mathbf{1 0} \boldsymbol{\&}$ <br> $\mathbf{1 1}$ | Females | 46.0 | 0.575 | -0.2 |
| $\mathbf{1 0 ~ \&}$ <br> $\mathbf{1 1}$ | Males | 40.0 | 0.68 | -0.25 |

## Maturity

In the northern Tyrrhenian Sea (GSA09), the reproduction area of $P$. longirostris is located from 150 to 350 m ; mature females are present all year round, even though the species shows two peaks in reproductive activity, one in spring and another at the beginning of autumn (Mori et al., 2000a). In the central Tyrrhenian Sea, the southern part of GSA 09, a main winter spawning was hypothesized (Ardizzone et al., 1990). The size at onset of sexual maturity estimated for different years in northern Tyrrhenian Sea is about 24 mm CL (Mori et al., 2000a). The number of oocytes in the ovary was related to the size of the females and ranged from 23,000 oocytes at 26 mm CL to 204,000 at 43 mm CL. An exponential relationship was observed between fecundity and carapace length: Fecundity $=0.0569 *$ CL4.0177 ( $r=0.829$ ) (Mori et al., 2000).

In the Central-Southern Tyrrhenian Sea (GSA10) the occurrence of mature females was observed in spring (May), summer (July-August) and autumn (October), with a higher relative frequency in spring-summer seasons (Spedicato et al., 1996). Thus, a continuous recruitment pattern is shown which, however, exhibits a main pulse in the autumn season. At 16 mm carapace length the pink shrimp is considered recruited to the grounds (SAMED, 2002). In GSA09, the main nurseries revealed a high spatio-temporal persistency between 60 and 220 m depth. Recruits (CL 15 mm ) occur all year round, with a main peak from July to October (De Ranieri et al., 1997).

The overall sex ratio is about 0.5.
The maturity proportion at age adopted in the present assessment is reported In Tab. 6.10.1.2.

Table 6.10.1.2 Deep-water rose shrimp in GSAs $09,10 \& 11$. Maturity proportion at age adopted in the present assessment.

## Ecology

P. longirostris diet is composed of a great variety of organisms; the prey items consisted mostly of external skeletons of bottom organisms, always crushed and often in an advanced state of deterioration. Crustaceans dominated the diet both qualitatively and quantitatively; they were characterized by a high abundance of peracarids, mainly represented by mysids (Lophogaster typicus) and amphipods (Lysianassidae). Molluscs (juvenile bivalves and gastropods), cephalopods (Sepiolids), small echinoderms, annelids, small fishes, foraminiferans, (Globigerinidae) and organic detritus are other important food item in the diet of the species (Mori et al., 2000b).

## Natural mortality

Natural mortality was estimated applying Chen \& Watanabe model. A curve by sex for each GSA has been estimated, and then a single $M$ vector was produced combining the vectors obtained by sex. The input growth parameters ( $k$ and $t_{0}$ ) used are reported in Tab. 6.10.1.1. The natural mortality vector by age is reported in Tab. 6.10.1.3.

Table 6.10.1.3 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Vector of natural mortality used in the present assessment.

| Age | 0 | 1 | 2 | 3 | $4+$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $M$ | 2.21 | 1.08 | 0.87 | 0.79 | 0.76 |

### 6.10.2 DATA

Deep-water rose shrimp is one of the most important target species of the bottom trawl fisheries carried out on the continental shelf and upper slope. Some catches coming from gillnet and trammel net are sporadically observed in GSAs 09 and 10.

### 6.10.2.1 CATCH (LANDINGS AND DISCARDS)

The annual total landing of Deep-water rose shrimp observed from 2002 to 2018 is reported in Fig. 6.10.2.1.1 and Tab. 6.10.2.1.1. The time series available in the DCF database are different for the three GSAs: 2003-2018 for GSA09, 2002-2018 for GSA10 and 2009-2018 for GSA11.

The landings coming from GSA11 are low in comparison with the other two GSAs. In the first years, the landing was higher in GSA10, and then, since 2010, GSA09 has become the most important in terms of biomass landed. The trend of the landing for the combined GSAs shows a significant decrease at the beginning of the series followed by some years of stability. Starting from 2010, a constant increase is observed until the maximum value registered in 2018. Anomalous values have been observed in 2002 and 2006 in GSA10.

Discard data (Tab. 6.10.2.1.1) are available in GSA09 since 2009. In this area this fraction of the catches ranged from 5 to $11 \%$ of the total biomass caught. In GSA10, where discard represents a lower percentage of the total catch (around 1-2\%), data are available since 2006. Data on discard are not available for GSA11. Missing discard data were not reconstructed.

Figure 6.10.2.1.1 Deep-water rose shrimp in GSAs 09, 10 \& 11. Annual landings from 2002 to 2018 by single and combined GSAs.

Table 6.10.2.1.1 Deep-water rose shrimp in GSAs 09, 10 \& 11. Annual catches ( t ) by GSA and fishing technique as provided through the official DCR-DCF database.

Annual landings in tonnes by year and fleet for the three GSAs are reported in Figs. 6.10.2.1.2-4. Annual discards in tonnes by year and fleet for GSA09 and GSA10 are displayed in Figs. 6.10.2.1.5-6.

Figure 6.10.2.1.2 Deep-water rose shrimp in GSAs 09, 10 \& 11. Annual landings in tonnes by year and fleet for GSA09.

Figure 6.10.2.1.3 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Annual landings in tonnes by year and fleet for GSA10.

Figure 6.10.2.1.4 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Annual landings in tonnes by year and fleet for GSA11.

Figure 6.10.2.1.5 Deep-water rose shrimp in GSAs 09, 10 \& 11. Annual discards in tonnes by year and fleet for GSA09.

Figure 6.10.2.1.6 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Annual discards in tonnes by year and fleet for GSA10.

Length frequency distributions of the commercial and discard fractions are displayed in Figs. 6.10.2.1.7-9.

Figure 6.10.2.1.7 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Size frequency distributions of landing (above) and discard (below) in GSA09.

Figure 6.10.2.1.8 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Size frequency distributions of landing (above) and discard (below) in GSA10.

Figure 6.10.2.1.9 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Size frequency distributions of landing in GSA11.

In GSA09, demographic structure of the landing is available for OTB in 2003 and 2004 and by metier from 2005 to 2018 (OTB_DEMF, OTB_DEMSP, OTB_DWSP and OTB_MDDWSP). Length frequency distributions of discard by metier are available from 2009.

In GSA10 the demographic structure of the landing is available for 2002 and for the period 20042018. Data by metier are available for the periods 2010-2012 and 2014-2018. Length frequency distributions for the other metiers are available for 2012 (gillnet). Size structure of the discard is available for 2006 and for the period 2009-2017.

In GSA11, length frequency distributions are present in the DCR-DCF database only for landing in the period 2009-2018.

### 6.10.2.2 EfFORT

Fishing effort data were reported through DCR-DCF database.
All the indicators related to the fishing effort showed a decreasing trend along the time series, more evident in the period 2004-2008. A similar trend is observed comparing the three GSAs.

The total fishing days of bottom trawling decreased in the period 2004-2012, passing from 146,048 to 91,913 . However, a slight recovery has been observed in recent years ( 100116 fishing days in 2017).

The nominal fishing effort of the trawl fleets operating in the three GSAs (kW* days at sea), has shown a progressive decrease in the period 2004-2011. It varied from about 30,597,000 in 2004 to $19,694,000$ in 2015 . In the last years the value remained quite constant.

The fishing effort expressed as GT*days at sea showed a decreasing trend from $2004(5,456,690)$ to $2011(3,687,969)$. In the last years the value fluctuated around $4,000,000$ and a slightly increase due to changes in the fleets of GSAs 10 and 11.

Anyway, there is no information on the specific effort directed to $P$. Iongirostris.

Figure 6.10.2.2.1 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Trends of fishing days, nominal effort and effort expressed in GT*days at sea for the three GSAs and for the whole area.

### 6.10.2.3 SURVEY DATA

## Survey \#1 (MEDITS)

Since 1994 MEDITS trawl surveys has been regularly carried out each year during the springsummer season.

### 6.10.2.3.1 Methods

Based on the DCF data, abundance and biomass indices for GSAs 09, 10 and 11 combined were calculated. In Tabs. 6.10.2.3.1.1-2 the number of hauls was reported per depth stratum in each GSA.

Table 6.10.2.3.1.1 Number of hauls per year and depth stratum in GSA09, period 1994-2018.

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).
The abundance and biomass indices by GSA were calculated through stratified means. This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
Yst $=\Sigma\left(\mathrm{Yi}{ }^{*} A \mathrm{i}\right) / \mathrm{A}$
$V(Y s t)=\Sigma\left(A i^{2} * s i^{2} / n i\right) / A^{2}$
Where:
A=total survey area
$s i=s t a n d a r d$ deviation of the $i$-th stratum $n i=n u m b e r$ of valid hauls of the $i$-th stratum
$\mathrm{n}=$ number of hauls in the GSA
Yst=stratified mean abundance $\quad V(Y s t)=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=\mathrm{Yst} \pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a deltadistribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial. Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance*100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA.

### 6.10.2.3.2 Geographical distribution

The following maps show the abundance (in biomass) per haul of the MEDITS survey standardized to square kilometre. It is evident as in the first years the abundance of Deep-water
rose shrimp was low in particular in the northern part of GSA09. Since 1998 the abundance of the species increased in the north-central Tyrrhenian Sea and along the south-western coasts of Sardinia. Since 2015, very high indices were observed for GSA09 including the northern part.

Figure 6.10.2.3.2.1 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Distribution pattern in the period 1994-2005 (MEDITS survey).

Figure 6.10.2.3.2.2 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Distribution pattern in the period 2006-2017 (MEDITS survey).

Figure 6.10.2.3.2.3 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Distribution pattern in the period 1994-2018 (MEDITS survey).

### 6.10.2.3.3 Trends in abundance and biomass

The trends of the MEDITS indices (density and biomass) for the three GSAs combined are displayed in Fig. 6.10.2.3.3.1. Both indices showed an evident increasing trend with very high values in the periods 2010-2013 and 2015-2018.

Figure 6.10.2.3.3.1 Deep-water rose shrimp in GSAs 09, 10 \& 11. MEDITS standardized abundance and biomass indices (10-800 m).

### 6.10.2.3.4 Trends in abundance and biomass by length

Figs. 6.10.2.3.4.1-3 display the stratified abundance indices by length for the three GSAs combined during the MEDITS surveys from 1994 to 2018.

Figure 6.10.2.3.4.1 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Stratified abundance indices by size for females, period 1994-2018.

Figure 6.10.2.3.4.2 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Stratified abundance indices by size for males, period 1994-2018.

Figure 6.10.2.3.4.3 Deep-water rose shrimp in GSAs $09,10 \& 11$. Stratified abundance indices by size for the total population, period 1994-2018.

### 6.10.3 Stock ASSESSMENT

A Statistical Catch-at-age (a4a) assessment was carried out during STECF EWG 19-10 using catch data collected under DCR-DCF from 2009 to 2018 and calibrated with survey data (MEDITS 20092018). FLR libraries were employed in order to perform the analyses.

A natural mortality vector computed using Chen and Watanabe model was used in the assessment. Length-frequency distributions of commercial catches (landing + discard) and surveys were split by sex (vectors from DCR-DCF database) and then transformed in age classes using length-to-age slicing with different growth parameters by sex. For the transformation of the frequency distributions into age classes, to growth parameter has been increased by 0.5 because the origin of growth is assumed to be at the peak of reproduction for this species which mainly occurs in summer, and the assessment year is from Jan to Dec. Plus group was set at age 4. The number of individuals by age was SOP corrected [SOP = Landings / $\Sigma$ a (total catch numbers at age a $x$ catch weight-at-age a)]. The correction factor resulted low. MEDITS data from the three GSAs for the period 2009-2018 were used for tuning.

Discards were included in the analysis with the exception of GSA11 for which data are not available. This information was not available in some years also for GSAs 09 and 10.
Given that the catches were composed mainly of individuals between 1 and 2 years, these ages were selected as the Fbar.

## Catches age structure

Figure 6.10.3.1 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Age frequency distributions of the total commercial catches (above) and of the MEDITS catches (below) by year.

The assessment was performed by sex combined. The model settings that minimized the residuals and showed the best diagnostics outputs were used for the final assessment, and are the following:

Fishing mortality sub-model:
fmodel <- ~ s(year, $k=6)+s($ year, $k=5$, by=as.numeric $(a g e==3))+s(y e a r, k=5$, by=as.numeric $($ age $==0)$ )
Catchability sub-model:

```
        qmodel <- list(~ factor(age))
```

Model <- a4aSCA(stock = stk, indices = idx, fmodel, qmodel)

The assessment results are shown in Figs. 6.10.3.2-12 and Tabs. 6.10.3.2-4.

| 2018 | 0.921 | 2887070 | 2336.3 | 9761.8 |

Based on a4a results, the Deep-water rose shrimp SSB showed an increasing trend, reaching the maximum value in 2018 ( 2336 tons). The recruitment (age 0) showed a similar trend of SSB, with a peak in 2016 ( $3,672,862$ thousands individuals) and a decreasing in the last two years. The lowest value of fishing mortality (Fbar $=0.67$ ) is observed in 2009. After that, a constant increase of $F$ was showed reaching the maximum value of 1.05 in 2014. In the following three years, Fbar decreased. In 2018, Fbar was 0.92.

### 6.10.4Reference Points

The STECF EWG 19-10 recommended to use $\mathrm{F}_{0.1}$ as proxy of $\mathrm{F}_{\mathrm{ms}}$. The library FLBRP available in FLR was used to estimate $\mathrm{F}_{0.1}$ from the stock object resulting from the outputs of the a4a assessment.

The yield per recruit (YpR) analysis was performed to estimate $\mathrm{F}_{0.1}$, chosen as proxy of $\mathrm{F}_{\text {msy }}$ and as the exploitation reference point consistent with high long-term yields. YpR output curve is illustrated in Fig. 6.10.4.1.

Current $F$ ( 0.92 ), estimated as the $F_{b a r 1-2}$ in the last year of the time series (2018), is lower than $F_{0.1}$ (0.97), which indicates that Deep-water rose shrimp stock in GSAs 9, 10 and 11 is exploited sustainability.

Figure 6.10.4.1 Deep-water rose shrimp in GSAs 09, $10 \& 11$. Yield per Recruit curve.

### 6.10.5ShORt term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the a4a stock assessment.

The input parameters for the deterministic short-term predictions for the period 2017 to 2019 were the same used for the a4a stock assessment and its results Table 6.10.5.1. An average of the last three years has been used for weight at age, maturity at age, and $\mathrm{F}_{\text {bar }}$.

Recruitment (age 0 ) has been estimated from the population results as the geometric mean of the whole data series (3101709 thousand individuals).

A short-term projection of the trawl fleet (Tab. 6.10.5.2) fishing at the status quo ( $\mathrm{F}=0.88$ ) generates a decrease of the catch of $14.1 \%$ from 2018 to 2020 along with an approximately stable spawning stock biomass (change $+2.7 \%$ ) from 2019 to 2021. Fishing at $F_{0.1}$ (0.97) generates a decrease of the catch of $8.5 \%$ from 2018 to 2020, while the spawning stock biomass remains quite stable from 2019 to 2021 (-1.0\%).

Table 6.10.5.1 Deep-water rose shrimp in GSAs 9, 10 and 11: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :---: | :---: | :---: |
| Biological Parameters |  | mean weights at age, maturation at age, natural mortality at age and selection at age, based average of 2016-2018 |

### 6.10.6 Data Deficiencies

Data from DCR-DCF database as submitted through the Official data call in 2019 were used for the stock assessment.

Landing data. The time series of landing data in biomass available in the database were different among the three GSAs: 2003-2018 for GSA09, 2002-2018 for GSA10 and 2009-2018 for GSA11.

The length frequency distributions of the landing for GSA09 are available for the period 20032018 (year 2002 is missing). For GSA10, data are not available for 2003. The historical data series for GSA11 includes the period 2009-2018 (the years 2002-2008 are missing). In GSA10, length frequency distributions and relative landings are missing for the third quarter of 2017 and for the first quarter of 2018. Although the assessment started from 2009, the lack of data in the previous years in GSA11 has a low impact as the landing in this area are very low if compared to those observed in GSA9 and GSA10. Concerning the lack of quarters in GSA10 in the last two years, a sop correction was necessary.

Discard data. The biomass discarded and the related length frequency distributions of Deep-water rose shrimp in GSA09 are available for the period 2009-2018. In GSA10, the data on discard are available for 2006 and for the years 2009-2017. The lack of data in 2018 for GSA10 had a low impact on the assessment as, on average, discard in GSA10 represents about $2 \%$ of the total catch. With regard to GSA11, there are no data on this fraction of the catch. Due to the low catches of DPS in GSA11 the discard of this species could be considered negligible in the area. It should be emphasized that the Italian national data collection program did not provide for the collection of discard before 2006 and in the years 2007-2008.

### 6.11 Red MuLLET IN GSA 9

### 6.11.1. Stock Identity and Biology

Red mullet (Mullus barbatus) is distributed in GSA 9 (Figure 6.11.1.1) along the shelf at depths up to 200 m , but mainly concentrated in the depth range $0-100 \mathrm{~m}$. EU project STOCKMED outcomes suggest a single stock unit in the GSA 9 and the rest of Western Mediterranean (see: https://ec.europa.eu/fisheries/documentation/studies/stockmed en). Available spatial information from MEDITS show continuous distribution of the red mullets along western Italian coast (i.e. connectivity of GSA9 with GSA 10) (Figure 6.11.1.2).

Figure 6.11.1.1 Location of GSA 9 in the Mediterranean Sea.

Figure 6.11.1.2 Geographical distribution of red mullet in the Mediterranean basin (kg/km ${ }^{2}$, average 2004-2014 by GFCM rectangle), STOCKMED Project.

However, in line with ToR given, EWG19-10 assumed here that inside the GSA 9 boundaries inhabits a single, homogeneous red mullet stock that behaves as a single well-mixed and selfperpetuating population. The hypothesis of a single stock of red mullet in GSA 9, which includes waters belonging to 2 different seas (Ligurian and Tyrrhenian) separated by the Elba Island as well as fleets that do not show any spatial overlapping is unlikely. The inability to account for spatial structure reduces flexibility and can lead to uncertainty in the definition of the status of the stocks, due to the possibility of local depletions and to a worse utilization of the potential productivity of the resources (STECF, 2014).

## Growth

Growth parameters of red mullet in GSA 9 were available from 2006 to 2018 (Figure 6.11.1.3) from DCF data. For the aim of the stock assessment a set of von Bertalanffy parameters given by the average along the years was used. It should be noticed that these growth parameters are quite different from the ones used for the neighbouring area (GSA 10; Section 6.12.1), that were consistent with the parameters estimated and validated by means of a set of different methods in Carbonara et al. (2018).

Figure 6.11.1.3. Estimated growth curves of red mullet in GSA9.

Differently from the previous assessment, the mean length at age 0 were re-examined in order to associate the age classes to the mean length at the end of the year, being the a4a model parameterized with calendar year. On the basis of the discussions, the EWG19-10 agreed to shift length slicing by adding a value of 0.5 to the t0 value used in previous assessment (set at -0.33 for both females and males) for internal consistency in the stock assessment model. The adjusted parameters, used in L2a length slicing for the assessment, are:

Linf=26.56, k=0.545, t0=0.17 for females; Linf=21.55, k=0.56, t0=0.17 for males.
Original growth curves are used to estimate natural mortality see below.
Length-weight relationships for females and males were: females: $\mathrm{a}=0.012, \mathrm{~b}=3$; males: $\mathrm{a}=$ $0.017, b=2.84$ (average of DCF data along the years 2002-2017).

## Natural mortality

Natural mortality (M) was estimated according to Chen and Watanabe model (1989) on the age vector at half year ( $0.5,1.5,2.5, \ldots$ ) using the orginal growth parameters, without the adjustement of the t 0 .

Linf=26.56, $k=0.545, t 0=-0.33$ for females; Linf=21.55, $k=0.56, t 0=-0.33$ for males.

## Maturity

Maturity ogives by age were available from 2006 to 2018 in the DCF data. The vector of matures by year and age showed a wide uncertainty especially on maturity at age 0 and 1 (Figure 6.11.1.4), that seems inconsistent with the growth curve and the spawning season of the species. For this reason the EWG preferred to use the vector of maturity agreed and used for all the red
mullet stocks assessed in the working group. Mortality and maturity parameters used in assessment are shown in Table 6.11.1.1.

Table 6.11.1.1 natural mortality and maturity vector at age.

| Age | 0 | 1 | 2 | 3 | $4+$ |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $M^{*}$ | 1.52 | 0.87 | 0.7 | 0.63 | 0.59 |
| Proportion <br> mature | 0 | 1 | 1 | 1 | 1 |

Figure 6.11.1.4. Maturity ogives by age and by years for red mullet in GSA 9.

### 6.11.2 DATA

### 6.11.2.1 CATCH (LANDINGS AND DISCARDS)

Principal fishing gears used to catch red mullet in GSA 9 together with other species (mixed catches) are gillnets (GNS), trammel nets (GTR) and bottom trawls (OTB). Length structure of red mullet catches (landings and discards) for all gears in the period from 2003 to 2018 are shown in Figures 6.11.2.1.1-6.11.2.1.3 for landings, discards and catches respectively.

Figure 6.11.2.1.1. Length structure of red mullet landed in GSA 9 in the period from 2003 to 2018 by fishing gear and fishery.

Figure
6.11.2.1.2. Length structure of red mullet catch discarded in GSA 9 in the period from 2006 to 2018 by fishing gear and fishery.

Figure 6.11.2.1.3. Length structure of red mullet total catch (landing plus discard) in GSA 9 in the period from 2003 to 2018 by fishing gear and fishery.

Discard of red mullet in GSA 9 occurs mainly from the catches of bottom trawls (OTB). Discard data were available in 2006, and for all years since 2009. For the assessment purposes, in the years where discard data were missing, approximations were made taking into account percentage of catch discarded in previous and/or following year.

### 6.11.2.2 EfFORT

Red mullet is caught by mixed fisheries, using more than a fishing gear (gillnets, trammel nets, trawls), by fishing boats of different sizes (different metiers, VL0006-VL1824). With the aim to associate effort data with particular stock assessments, based on local expert knowledge, EWG19-10 made a selection of gear types in different GSAs. Effort data for Mullus barbatus for GSA 9 are reported in Figure 6.11.2.2.1 and in Tables 6.11.2.2.1. and 6.11.2.2.2 for fishing days and days at sea respectively.
However, EWG19-10 also highlights that gears indicated in the table are used in framework of different fisheries where multispecies catches are obtained. So, it is important to keep in mind that fishing effort data, that according to ToR 3 is analysed on fishing gear level, are related to multifisheries and multispecies aspects, and not just to one single species considered in the assessments.

Fishing effort - GNS \& GTR \& OTB in GSA 9 (ITA)

6.11.2.3 SURVEY DATA

Survey indices used in this assessment originate from MEDITS scientific bottom trawl survey. These surveys in GSA9 took place in different seasons of the year (Fig. 6.11.2.3.1). EWG19-10 considered this fact during interpretation of available survey indices in the assessment excluding age 0 in the tuning index, because not intercepted every year. In addition, the EWG19-10 attempted to include the Italian GRUND survey (1994-2008, and until 2006 in GSA 9) in the analysis, in order to use the information collected by RECFISH project and to increase the model performance. This attempt was also done because the GRUND survey generally was carried out in autumn and, thus, it was possible that the recruits were detected more regularly than with the MEDITS. However, the analyses revealed that the GRUND survey was not informative for the model, and it was not included in the final model run.

Figure 6.11.2.3.1 Survey periods of MEDITS in GSA 9.

Analyses of available MEDITS data show large variations between years (Figs. 6.11.2.3.2 and 6.11.2.3.3). An increase in red mullet density index (abundance and biomass) can be noticed from 2014 onward, with peaks in 2014 and 2017.

However, in relation to MEDITS data available, EWG19-10 also noted very different survey periods in these two years, concluding that autumn survey in 2017 probably recorded red mullet recruits that were not recorded by 2016 spring survey. This is reflected in the size structure indices of red mullet in GSA 9, as derived from trawl surveys (MEDITS, 1994-2018), shown in Figure 6.11.2.3.6. Large inter-annual variations in length structure can be noticed due to the survey time, that in some years allowed to detect the recruitment of the species.

### 6.11.3 STOCK ASSESSMENT

The present assessment of red mullet in GSA 9 has been based on a4a model. The a4a model is a flexible statistical catch at age stock assessment model, based on linear modelling techniques, not working by gear. The method was developed within FLR framework.
Input data considered (landing, discard, age, maturity, MEDITS) originate from DCF Med\&BS data call and cover the years 2003-2018. Despite availability of commercial fishery data since 2003, the assessment was carried out from 2004 in accordance with EWG 18-12, for which the inclusion of 2003 resulted in worse model fit than excluding this year.

Age slicing using a4aGr of the length frequency distributions of landing, discard and survey has been carried out by sex (in combination with sex ratio at length) using a4aGr model and then data were combined. The final catch at age data are shown in the figure 6.11.3.1. In comparison with EWG18-12, the catches at age resulted more abundant in age class 1 due to the shift in the growth curve.

Table 6.11.3.1. Values of catch at age per year used in the assessment.

|  | Age |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
|  | 0 | 1 | 2 | 3 | 4 |
| 2004 | 1840.014 | 15919.84 | 3898.417 | 299.6835 | 114.9868 |
| 2005 | 1284.906 | 15917.53 | 6434.742 | 312.9313 | 9.2499 |

Figure 6.11.3.1. Catch-at-age data of red mullet in GSA9 used in assessment.

Survey indices (density by age) from MEDITS were used considering that spring surveys are not designed to detect recruitment of red mullet. Recruitment (age class 0 ) was detected just in some
years when surveys were carried out in late summer or autumn. Due to the variability of survey timing, age 0 class was not included in the tuning indices used for the assessment. MEDITS indices (density by age) are shown in figure 6.11.3.2.

Figure 6.11.3.2 MEDITS indices describing density by age of red mullet in GSA9 by year.

For the assessment purposes, different F, q and sr bub-model were explored. Among them, the ones retunring the most consisten tresults in terms of residuals and retrospective are:

Fmodels

- fmod $1<-\sim s($ replace $($ age, age $>2,2), k=3)+s(y e a r, k=6)$
- fmod2<- ~s(replace(age, age > 2, 2), k = 3) + s(year, k=6) + te(age, year, $k=c(3,7))$

## qmodels

- qmod1<- list( $\sim$ factor(replace(age,age>2,2)))
- qmod2<- list( $\sim 1$ )

## SRmodels

- srmod1 <- ~factor(year)
- srmod2 <-~s(year,k=4)
- srmod3 <- ~ geomean(CV=0.3)

All the combinations of the 7 sub-models were tested, compared and evaluated according to the quality of residuals and retrospective analysis.

The best fit was obtained:

- fmodel: $\sim s($ age, $k=3)+s(y e a r, k=3)+$ te(age, year),
- srmodel: $\sim s(y e a r, k=4)$
- qmodel: $\sim 1$.

Results are shown below (Figure 6.7.5.3).

Figure 6.11.3.3 Results of the best a4a model for red mullet in GSA9.
The results of the retrospective analysis are shown in Figure 6.11.3.4.
Log residuals of the catch and abundance indices related to outcomes of the best run do not show any particular trend and they are shown in Figure 6.11.3.5.

Figure 6.11.3.4 Retrospective analysis of the selected a4a model for red mullet in GSA9.

Figure 6.11.3.5. Log residuals of catch and abundance indices for red mullet in GSA9.

Final assessment outcomes are given in Table 6.11.3.4.

### 6.11.4 Reference Points

The time series is too short to produce meaningful stock recruitment rationship, so reference points are based on equilibrium methods. The STECF EWG recommended to use $\mathrm{F}_{0.1}$ as proxy of FMSy. The library FLBRP available in FLR was used to estimate F $_{0.1}$ from the stock object resulting from the outputs of the 6.11.3 assessment.

Values of Fo.1 calculated by FLBRP package on the a4a assessment results is equal to 0.58. Current F values (2018), as calculated by model a4a, is 1.58 indicating that the stock is being overfished.

### 6.11.5 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the stock assessment.

The basis for the choice of values is given in Section 4.3. An average of the last three years has been used for weight at age, maturity at age, while the $\mathrm{F}_{\mathrm{bar}}=1.58$ terminal F (2018) from the a4a assessment was used for $F$ in 2019. Recruitment is observed to be fluctutating over the period of the assessment (Figure 6.11.3.3) so the average across the whole time series is used as an estimate of recruits from 2019. Recruitment (age 0) for 2019 to 2021 has been estimated from the population results as the geometric mean of the whole time series of 15 years (275835).

Table 6.11.5.1 Red mullet in GSA 9: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological <br> Parameters | average of <br> $2016-2018$ | mean weights at age, maturation at age, natural mortality <br> at age and selection at age |
| Fages 1-3 (2019) | 1.58 | F 2018 used to give F status quo for 2019 |
| SSB (2019) | 641 | Stock assessment 1 January 2019 |
| Rageo (2019,2021) | 275835 | Geometric mean of the time series last 15 years |
| Total catch (2019) | 1100 | Assuming F status quo for 2019 |

The short term forecast was carried out estimating a catch for 2018-2020 on the basis of a recruitment hypothesis constant and equal to the mean on the whole time series and an F by age equal to that of the terminal year. These assumptions resulted in a catch and a SSB in 2019 equal to 1100 and 641 tons, respectively.
The analysis, carried out with stf.r FLR script made available to the EWG, shows that fishing at a level equal to $\mathrm{F}_{0.1}(=0.58$ ) would increase biomass of $86 \%$ from 2019 to 2021, while decreasing the catch of the $63 \%$ from 2018 to 2020.

Table 6.11.5.2 - Short term forecast table for red mullet in GSA 9.
$\left.\begin{array}{|c|c|c|c|c|c|c|c|c|}\hline \text { Rationale } & \text { Ffactor } & \text { Fbar } & \begin{array}{c}\text { Catch } \\ 2018\end{array} & \begin{array}{c}\text { Catch } \\ 2020\end{array} & \begin{array}{c}\text { SSB* } \\ 2019\end{array} & \begin{array}{c}\text { SSB* } \\ 2021\end{array} & \begin{array}{c}\text { Change } \\ \text { SSB } \\ 2019-2021 \\ (\%)\end{array} & \begin{array}{c}\text { Change } \\ \text { Catch } \\ \text { 2018-2020 } \\ (\%)\end{array} \\ \hline \begin{array}{c}\text { High long } \\ \text { term yield } \\ \text { (Fo.1) }\end{array} & 0.4 & 0.58 & 1393 & 512 & 937 & 1226 & 86 & -63\end{array}\right]$
*SSB at mid year
EWG advises that when the MSY approach is applied, catches in 2020 should be no more than 512 tonnes.

### 6.11.6 Data Deficiencies

The EWG19-10 did not find any particular data deficiency for this stock, in terms of data quality.

### 6.12 RED MULLET IN GSA 10

### 6.12.1 Stock Identity and Biology

Red mullet (Mullus barbatus) is distributed in GSA 10 along the shelf at depths up to 200 m , but mainly concentrated in the depth range 0-100 m. The area of GSA 10 extends in the South and Central Tyrrhenian Sea, that features one of the most complex structures in the seas around the Italian peninsula, due to its morphological and geophysical characteristics and water mass dynamics (Cataudella and Spagnolo, 2011). In line with the given ToR, it is assumed in the present assessment that inside the GSA 10 boundaries inhabits a single, homogeneous red mullet stock that behaves as a single well-mixed and self-perpetuating population.
However, the EWG19-10 noticed that EU project STOCKMED outcomes suggest a single stock unit in Western Mediterranean
(see: https://ec.europa.eu/fisheries/documentation/studies/stockmed_en). In addition, available spatial information from MEDITS show continuous distribution of the red mullets along western Italian coast (i.e. continuity in spatial distribution in GSA10 and GSA9).

Figure 6.12.1.1. Map of GSA 10.

## Growth

The information on the age-length key (ALK) and on the growth von Bertalanffy parameters was available from 2002 and appeared consistent with the recent study of Carbonara et al. (2018) on age validation of red mullet in Adriatic Sea.

Growth parameters reported in DCF are: females: $\operatorname{Linf}=30, \mathrm{k}=0.243, \mathrm{t} 0=-0.62$; males: $\operatorname{Linf}=26$, $\mathrm{k}=0.237, \mathrm{t} 0=-0.9$.

In contrast with the previous EWG, the EWG19-10 agreed that no adjustment of t0 was needed to parameterize the stock assessment model (a4a) to work with calendar year, being the mean length at age derived by the DCF von Bertalanffy growth curve already in line with the mean length expected at the end of the year.

## Natural mortality

Natural mortality (M) was estimated according to Chen and Watanabe model (1989) on the age vector at half year $(0.5,1.5,2.5, \ldots)$ using the same growth parameters used in the slicing.

## Maturity

Maturity ogives by length and age were available from 2002 to 2018 by sex. Data until 2017 are quite consistent with the maturity vector agreed within the EWG 18-12, while data in 2018 show an incosistent pattern (Figure 6.12.1.2). The EWG19-10 applied the vector used in previous years. Mortality and maturity parameters used in assessment are shown in Table 6.12.1.1.

Figure 6.12.1.2. Maturity at age for Mullus barbatus in GSA 10.

Table 6.12.1.1 natural mortality and maturity vector by age used in the stock assessment.

| Age | 0 | 1 | 2 | 3 | $4+$ |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $M^{*}$ | 1.44 | 0.75 | 0.57 | 0.48 | 0.43 |
| Proportion <br> mature | 0 | 1 | 1 | 1 | 1 |

### 6.12.2 DATA

### 6.12.2.1 CATCH (LANDINGS AND DISCARDS)

Principal fishing gears used to catch red mullet, together with other species (mixed catches) are gillnets (GNS), trammel nets (GTR) and bottom trawls (OTB). Length structure of red mullet landings and discards for all gears in the period from 2002 to 2018 are shown in Figures 6.12.2.1.1 and 6.12.2.1.2 for landing and discards, respectively, and in 6.12.2.1.3 for combined landing plus discards.

Figure 6.12.2.1.1. Length structure of red mullet landed in GSA 10 in the period from 2002 to 2018 by fishing gear and fishery.

Figure 6.12.2.1.2. Length structure of discarded catch of red mullet in GSA 10 in the period from 2006 to 2018 by fishing gear and fishery.

Figure 6.12.2.1.3. Length structure of catches (landing+discarded catch) of red mullet in GSA 10 in the period from 2006 to 2018 by fishing gear and fishery.

The discard data, in the years where it was not available, were reconstructed on the basis of the closest discard data available, and included in the assessment.

### 6.12.2.2. EFFORT

Red mullet is caught by mixed fisheries, using more than a fishing gear (gillnets, trammel nets, trawls), by fishing boats of different sizes (different metiers, VL0006 - VL1824). With the aim to associate effort data with particular stock assessments, based on local expert knowledge, EWG19-10 made a selection of gear types in different GSAs. Effort data for Mullus barbatus for GSA 10 are reported in figure 6.12.2.2.1 and table 6.12.2.2.1. However, EWG19-10 also highlights that gears indicated in the table are used in framework of different fisheries where multispecies catches are obtained.

Fishing effort - GNS \& GTR \& OTB
in GSA 10 (ITA)

### 6.12.2.3 SURVEY DATA

Survey indices used in this assessment originate from demersal trawl surveys, DCF-MEDITS. These surveys in GSA10 took place in different seasons of the year (Figure 6.12.2.3.1). EWG1910 considered this fact during interpretation of available survey indices in the assessment not including age 0 in the tuning index, because not intercepted every year. Analyses of available MEDITS data show large variations between years (Figures 6.12.2.3.2-6.12.2.3.3). In addition, the EWG19-10 attempted to include the Italian GRUND survey (1994-2008) in the analysis, using the information collected by RECFISH project, in the attempt of increasing the model performance. Indeed, GRUND survey was generally carried out in autumn, thus the detection more frequent of the recruitment, could improve the estimation of the recruitment also in the model. However, the analyses revealed that the GRUND survey was not informative for the model, and it was therefore not included in the final model run.

Figure 6.12.2.3.1. Survey periods (MEDITS, 1994-2018) in GSA 10.

Figure 6.12.2.3.2. Abundance indices ( $\mathrm{N} / \mathrm{km}^{2}$ ) of red mullet in GSA 10 as derived from trawl surveys (MEDITS, 1994-2018).

Figure 6.12.2.3.3. Biomass indices $\left(\mathrm{kg} / \mathrm{km}^{2}\right)$ ) of red mullet in GSA 10 as derived from trawl surveys (MEDITS, 1994-2018).

Figure 6.12.2.3.4. Abundance indices ( $\mathrm{N} / \mathrm{km}^{2}$ ) of red mullet in GSA 10 as derived from trawl surveys (GRUND, 1985-2008).

Figure 6.12.2.3.5. Biomass indices ( $\mathrm{kg} / \mathrm{km}^{2}$ )) of red mullet in GSA 10 as derived from trawl surveys (GRUND, 1985-2008).

Size structure indices of red mullet in GSA 10, as derived from trawl surveys (MEDITS, 19942018), are shown in Figure 6.12.2.3.6. Large inter-annual variations in length structure can be noticed due to the survey time, that in some years allowed to detect the recruitment of the species.

Figure 6.12.2.3.6. Size structure indices of red mullet in GSA 10 as derived from trawl surveys (MEDITS, 1994-2018).

### 6.12.3 StOCK ASSESSMENT

The present assessment of red mullet in GSA 10 has been based on a4a model. The a4a model is a flexible statistical catch at age stock assessment model, based on linear modelling techniques, not working by gear. The method was developed within FLR framework.
Input data considered (landing, discard, age, maturity, MEDITS) originate from DCF Med\&BS data call. Commercial fishery data are available since 2002. While in previous years the assessment was performed since 2004, EWG19-10 included 2002 and 2003 data in the assessment, not occuring the same convergence problems of the last years.

Table 6.12.3.1. Values of catch at age per year used in the assessment.

|  | Age |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
|  | 0 | 1 | 2 | 3 | 4 |

| 2018 | 31.15 | 49.95 | 111.31 | 48.03 | 27.68 |

Age slicing of the length frequency distributions of landing, discard and survey has been done by sex (in combination with sex ratio at length) using a4aGr model and then data were combined. The final catch at age data are shown in the Figure 6.12.3.1 and Table 6.12.3.1. The corresponding mean weights at age ate shown in Table 6.12.3.2.
The landing and discard of 2017 data was incomplete, because the third quarter data was missing.

After the request of the working group to the MS to provide the landing data, it was possible to derive the discard in the third quarter of 2017; this reconstruction was influential, being the third quarter the most important in terms of discard, due to the recruitment. The landing data, sent in due time by the MS, were also used to complete the official time series of 2018 , for which the first quarter was missing.

Survey indices (density by age) from MEDITS were used considering that spring surveys are not designed to detect recruitment of red mullet. Recruitment (age class 0) was detected just in some years when surveys were carried out in late summer or autumn. For that reason, age 0 class was not included in the tuning indices used for the assessment. MEDITS indices (density by age) are shown in Figure 6.12.3.2 and Table 6.12.3.3.

Figure 6.12.3.1. Catch-at-age data of red mullet in GSA10.

Figure 6.12.3.2. MEDITS indices describing density by age of red mullet in GSA10 by years.

For the assessment purposes, different $F$, $q$ and $s r$ sub-model were explored. Among them, the ones returning the most consistent results in terms of residuals and retrospective are:

## Fmodels

- fmod1<- $\sim s($ age, $k=3)+s($ year, $k=4)+$ te(age, year)
- fmod2<- ~s(age, k=3, by = breakpts(year, 2012)) + te(age, year)
- fmod3<- $\sim s($ replace(age, age $>3,3), k=3)+s(y e a r, k=6)$
qmodels
- qmod1<- list(~factor(replace(age, age > 2, 2)))
- qmod2<- list( $\sim 1$ )

## SRmodels

- srmod1 <- ~s(year,k=7)
- $\quad$ srmod2 <- ~geomean(CV=0.1)
- srmod3 <- ~geomean(CV=0.3)

All the combinations of the 8 sub-models were tested, compared and evaluated according to the quality of residuals and retrospective analysis.

The best fit was obtained using:
fmodel: ~ s(replace (age, age $>3,3$ ) $k=3$ ) $+\mathrm{s}($ year, $k=6)$
qmodel: list(~factor(replace(age, age > 2, 2)))
srmodel: $\sim$ geomean $(C V=0.3)$

Results are shown below (Figure 6.12.3.4).

Figure 6.12.3.4. Results of the best a4a model outcomes for red mullet in GSA10.

Figure 6.12.3.5. Retrospectve analysis of the best a4a model outcomes for red mullet in GSA10.

Log residuals of the catch and MEDITS abundance indices related to the best run do not show any particular trends over time with the possible exception of catch at ages 1 and 3 (Figure 6.12.3.6), however the fit to overall catch and to survey showed no trend. This choice is supported by the reasonable retrospective performance. The final assessment outcomes are given in summary in Table 6.12.3.4 and as $N$ and $F$ at age in Tables6.12.3.5 and 6.12.3.6 respectively.

### 6.12.4 Reference Points

The time series is too short to produce meaningful stock recruitment rationship, so reference points are based on equilibrium methods. The STECF EWG recommended to use $\mathrm{F}_{0.1}$ as proxy of Fmsy. The library FLBRP available in FLR was used to estimate $\mathrm{F}_{0.1}$ from the stock object resulting from the outputs of the 6.12.3 assessment.
The value of $\mathrm{F}_{0.1}$ calculated by FLBRP package on the a4a assessment results is equal to 0.41 . The $F$ value estimated for 2018, as calculated by a4a, is 0.48 , indicating that the current fishing mortality ( F ) is slightly above $\mathrm{F}_{0.1}$ reference point. Given that the fishing mortality has declined in the past years, and that catches are stable, this might be due to changes in the age structure of the stock, as confirmed by the decline in recruitment.

### 6.12.5 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the stock assessment.
The basis for the choice of values is given in Section 4.3. An average of the last three years has been used for weight at age, maturity at age, while the $\mathrm{F}_{\mathrm{bar}}=0.48$ terminal $F$ (2018) from the a 4 a assessment was used for F in 2019. Recruitment is observed to be fluctutating over the period of the assessment (Figure 6.12.3.4) so the average across the whole time series is used as an estimate of recruits from 2019. Recruitment (age 0) for 2019 to 2021 has been estimated from the population results as the geometric mean of the whole time series of 17 years (120897.6).

Table 6.12.5.1 Red mullet in GSA 10: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological <br> Parameters | average of <br> $2016-2018$ | mean weights at age, maturation at age, natural mortality <br> at age and selection at age |
| Fages 1-3 (2019) | 0.48 | F 2018 used to give F status quo for 2019 |
| SSB (2019) | 740 | Stock assessment 1 January 2019 |
| Rageo (2019,2020) | 120898 | Geometric mean of the time series 17 years 2002-2018 |
| Total catch (2019) | 369 | Assuming F status quo for 2019 |

These assumptions resulted in a catch and a SSB in 2019 equal to 369 and 740 tons, respectively.
The analysis, carried out with stf.r FLR script made available to the EWG, shows that fishing at a level equal to $\mathrm{F}_{0.1}$ ( $=0.41$ ) would increase the SSB of the $3 \%$ from 2019 to 2021, while decreasing the catch by the $23 \%$ from 2018 to 2020.

Table 6.12.5.2 - Short term forecast table for red mullet in GSA 10.

| Rationale | Ffactor | Fbar | $\begin{aligned} & \text { Catch } \\ & \text { On18 } \end{aligned}$ | $\begin{aligned} & \text { Catch } \\ & 2020 \end{aligned}$ | $\begin{aligned} & \text { SSB* } \\ & 2019 \end{aligned}$ | $\begin{aligned} & \text { SSB* } \\ & 2021 \end{aligned}$ | Change SSB $2019-2021$ $(\%)$ | Change Catch $2018-2020$ $(\%)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| High long term yield (Fo.1) | 0.9 | 0.41 | 403 | 309 | 763 | 780 | 2.58 | -23.18 |

|  | 2 | 0.95 | 403 | 578 | 594 | 468 | -38.43 | 43.35 |

*SSB at mid year
EWG advises that when the management strategy is applied, catches in 2020 should be no more than 309 tonnes.

### 6.12.6 Data Deficiencies

EWG19-10 has noted that landing and discard data of the $3^{\text {rd }}$ quarter of 2017 were missing for all gears and fisheries, as well as the landing and discard of the first quarter 2018. The missing landing data were requested to the Member State and received in the due time to carry out the assessment. Being available the landing data of the third quarter in 2017, the discard of the third quarter was estimated.

Despite these deficiencies, addressed on time for the analyses, an uncommon length structure (between 15 and 20 cm ) associated to the discard of the GTR with vessel length VL0006 in 2018 was noticed in quarter 4. Even the ratio between discard and landing for this stratum seems considerably high (D/L around 400\%) for the type of fishery. This anomaly seems due to the only 4 individuals sampled in the discard in only 1 sample collected in the stratum.

The EWG19-10 reported on line via the Data Transmission Monitoring Tool (DTMT) available at https://datacollection.jrc.ec.europa.eu/web/dcf/dtmt.

### 6.13 NORWAY LOBSTER IN GSA 9

### 6.13.1 Stock Identity and Biology

Due to a lack of information about the structure of $N$. norvegicus population in the western Mediterranean, this stock was assumed to be confined within the GSA 9 boundaries (Figure 6.11.1.1).

Figure 6.13.1.1 Limit of Geographical Sub-Area (GSA) 9.

### 6.13.1.1 GROWTH, MATURITY AND NATURAL MORTALITY

For $N$. norvegicus, there is a difference in growth between males and females. Males attaining greater lengths at ages and maximum sizes compared to females. Growth parameters for $N$. norvegicus in GSA 9 are provided in Table 6.18.1.1

Several sets of VBGF parameters have been reported in the DCF database. Also for the LengthWeight relationship, several sets of paramentes by sex are provided for GSA 9.
The VBGF and LW relationship parameters used for the assessment are summarized in the following table (Table 6.18.1.1).

Table 6.13.1.1 Norway lobster in GSA 9: VBGF and LW relationship parameters.

|  |  | Units | Females | Males |
| :---: | :---: | :---: | :---: | :---: |
| VBGF parameters | $\mathbf{L}_{\infty}$ | mm | 56.0 | 72.1 |
|  | $\mathbf{k}$ | years $^{-1}$ | 0.21 | 0.17 |
|  | $\mathbf{t}_{\mathbf{0}}$ | years | 0.0 | 0.0 |
| LW <br> relationship | $\mathbf{a}$ | $\mathrm{mm} / \mathrm{g}$ | 0.00032 | 0.00038 |
|  | $\mathbf{b}$ | $\mathrm{~mm} / \mathrm{g}$ | 3.24848 | 3.18164 |

A vector of proportion of mature by age was computed as a weighed average of the vectors available from the DCF database in GSA 9.
A natural mortality vector was estimated by sex using the Chen and Watanabe equation and the growth parameters described above. A combined natural mortality vector was then computed as a weighed average of the vectors by sex.
The vector of proportion of mature and the natural mortality vector used in the assessment of Norway lobster in GSA 9 are shown in Table 6.18.1.2.

Table 6.13.1.2 Norway lobster in GSA 9: natural mortality and proportion of mature vectors by age.

| Age | Natural <br> mortality | Proportion of <br> matures |
| :---: | :---: | :---: |
| 1 | 0.75 | 0.40 |
| 2 | 0.50 | 0.75 |
| 3 | 0.39 | 1.00 |
| 4 | 0.33 | 1.00 |
| 5 | 0.26 | 1.00 |
| 6 | 0.24 | 1.00 |
| 7 | 0.23 | 1.00 |
| $9+$ |  | 1.00 |

### 6.13.2 DATA

### 6.13.2.1 CATCH (LANDINGS AND DISCARDS)

The annual total landings of Norway lobster available in the DCF database are reported in Table 6.13.2.1.1 and Figure 6.13.2.1.1. In general, landings are showing a decreasing pattern along the time series, with a sharp increase in the last two years. The time series of landings by gear are shown in Figure 6.13.2.1.2.

Landings of Norway lobster in GSA 9 in the period 1994-2002 were gathered from the Italian official statistics (prior to DCR/DCF) which were collected and stored under the RECFISH project (Ligas, 2019).

Figure 6.13.2.1.2. Norway lobster in GSA 9: landings trend by gear in GSA 9.

Although the bulk of the production in GSA 9 is coming from the trawl fisheries (mostly demersal species and mixed demersal and deep-water species trawling), other fisheries (mostly gill nets) provide some contribution to the total production.

Table 6.13.2.1.3. Norway lobster in GSA 9: landings by gear.

| year | GSA 9 | Other |
| :---: | :---: | :---: |
| 2003 | 320.9 | 5.54 |
| 2004 | 268.7 | 0.11 |
| 2005 | 288.5 | 0.83 |
| 2006 | 247.5 | 0.09 |
| 2007 | 260.5 | 0.00 |
| 2008 | 227.7 | 0.04 |
| 2009 | 250.3 | 0.04 |
| 2010 | 161.6 | 0.04 |
| 2011 | 184.0 | 0.04 |
| 2012 | 178.2 | 0.34 |
| 2013 | 147.6 | 0.00 |
| 2014 | 111.6 | 0.07 |
| 2015 | 113.6 | 0.00 |
| 2016 | 130.9 | 0.00 |
| 2017 | 273.8 | 0.00 |
| 2018 | 223.2 | 0.00 |

Table 6.13.2.1.4. Norway lobster in GSA 9: landings from Italian official statistics as collected by the RECFISH project.

| year | OTB |
| :---: | :---: |
| 1994 | 376.4 |
| 1995 | 345.4 |
| 1996 | 359.5 |
| 1997 | 727.6 |
| 1998 | 225.5 |
| 1999 | 178.6 |
| 2000 | 334.9 |
| 2001 | 269.5 |
| 2002 | 276.8 |

Landings in 1997 were considered misreported. Checking the data it was pointed out that the landings reported in two ports were unreliably high compared to the other ports and the time series. Therefore the value was re-estimated for being used in the assessment.
The size structures by year and gear are shown in Figures 6.18.2.1.5-6.18.2.1.7.
LFDs for the period 1994-2002 were provided by the results of the RECFISH project (Ligas, 2019), who collected historical fishery information from previous projects and studies performed in the Mediterranean and Black Sea.

Figure 6.13.2.1.3. Norway lobster in GSA 9: LFDs of landings by year provided by the RECFISH project.

Figure 6.13.2.1.4. Norway lobster in GSA 9: LFDs of landings by year and gear of Norway lobster in GSA 9.

Discards of Norway lobster are low. Low values of discards (from OTB) are reported in GSA 9 from 2009 onwards. The discards are summarized in Table 6.18.2.1.2. Despite the low values of discards, LFDs are available, and the data were included into the stock assessment. LFDs of discards of Norway lobster are shown in Figure 6.18.2.1.8.

Table 6.13.2.1.5. Norway lobster in GSA 9: Discards by GSA.

| year | GSA9 <br> discards <br> $(\mathbf{t})$ |
| :---: | :---: |
| 2003 | 0.0 |
| 2004 | 0.0 |
| 2005 | 0.0 |
| 2006 | 0.0 |
| 2007 | 0.0 |
| 2008 | 0.0 |
| 2009 | 9.2 |
| 2010 | 0.9 |
| 2011 | 1.0 |
| 2012 | 0.8 |
| 2013 | 1.3 |
| 2014 | 0.4 |
| 2015 | 0.1 |

| 2018 | 0.7 |
|  |  |

Figure 6.18.2.1.5. Norway lobster in GSA 9: LFDs of discards of Norway lobster in GSA 9.

### 6.13.2.2 EfFORT

The total nominal effort of the trawl fleets operating in GSA 9, expressed as kW*fishing days, has shown a progressive decrease in the period 2002-2018. It varied from about 15,000,000 in 2002 to $9,500,000$ in 2018. In Table 6.18.2.2.1 and Figure 6.18.2.2.1, nominal effort is reported in ' 000 kW*fishing days, in Table 6.18.2.2.2 and Figure 6.18.2.2.2, nominal effort is reported in Days at sea. There is no information on the specific effort directed to giant red shrimp.

Table 6.13.2.2.1. Norway lobster in GSA 9: Summary of the OTB nominal effort (kW*fishing days, in thousands) by year in GSA 9.

| Year | GSA 9 |
| :---: | :---: |
| 2002 | 14583.6 |
| 2003 | 14671.0 |
| 2004 | 14820.3 |
| 2005 | 14700.6 |

### 6.13.2.3 SURVEY DATA

Since 1994, MEDITS trawl surveys have been regularly carried out each year (centred in the early summer). A random stratified sampling by depth (five strata with depth limits at 50, 100, 200, 500 and 800 m ) is applied. Haul allocation was proportional to the stratum area. All the
abundance data (number and total weight of fish per surface unit) are standardized to the $\mathrm{km}^{2}$ using the swept area method.

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance*100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the three GSAs.

## Geographical distribution

The following maps show the biomass indices ( $\mathrm{kg} / \mathrm{km}^{2}$ ) by haul of the MEDITS survey. It is evident as the giant red shrimp is more abundant in GSAs 10 and 11 than in GSA 9. Furthermore, the species is mostly present in the southern part of the GSA 9 (Masnadi et al., 2018).

Figure 6.13.2.3.1 Norway lobster in GSA 9: distribution pattern in the period 1994-2018 (MEDITS survey). Maps for the years 1994, 2002, 2010 and 2018 are shown.

## Trends in abundance and biomass

The trends of the MEDITS indices (biomass and density) computed on the three GSAs combined are shown in Figure 6.18.2.3.2.

The time series are characterized by wide fluctuations. A first evident peak is observed in 2000, then in 2005 and 2010. Despite a further peak in 2013, the trend from 2010 onward follows a decreasing pattern. The biomass and density indices obtained from 2014 onwards are among the lowest observed in the whole time series of the MEDITS data in GSAs 9, 10 and 11. In 2018, a sharp increase in biomass and density was observed.

Figure 6.13.2.3.2. Norway lobster in GSA 9: MEDITS standardized biomass and density indices (10-800 m).

Trends in abundance and biomass by length
The stratified abundance indices by length (by sex and total) computed on the three GSAs combined during the MEDITS surveys from 1994 to 2018 are shown in Figures 6.18.2.3.36.18.2.3.5. Also these plots show that the densities observed from 2014 onwards are among the lowest observed in the whole time series of the MEDITS survey in the GSAs 9, 10, 11.

Figure 6.13.2.3.5 Norway lobster in GSA 9: total stratified abundance indices by size, 1994-2018.

### 6.13.3 STOCK ASSESSMENT

FLR libraries were employed in order to carry out a Statistical Catch-at-age (a4a) assessment.
The assessment by means of a4a was carried out using as input data the period 1994-2018 for the catch data and 1994-2018 for the tuning file (MEDITS indices). This is a considerable extention to the series tried in 2018 which was 2003 to 2017.
A natural mortality vector computed using Chen and Watanabe model was estimated and used in the assessment. Natural mortality vector and proportion of mature are described in section 6.18.1.1. Length-frequency distributions of commercial catches and surveys were split by sex and then transformed in age classes (plus group was set at age 4) using length-to-age slicing with different growth parameters by sex. A correction of 0.5 was applied to to to account for spawning at middle year.
Landings in 1997 (reported in the Italian official statistics) were considered misreported. Checking the data it was pointed out that the landings reported in two ports were unreliably high compared to the other ports and the time series. Therefore the value was re-estimated for being used in the assessment.

The number of individuals by age was SOP corrected [SOP = Landings / $\Sigma a$ (total catch numbers at age a x catch weight-at-age a)]. However, the correction factor resulted low.
In catches, a plus group at age 9 was set, while the age structure in the MEDITS survey was from age 1 to age 8 .

Fbar range was fixed at 2-6.

The assessment was performed by sex combined. Given that the landings were composed mainly of individuals between 2 and 6 years, these ages were selected as $F_{b a r}$ range.

The model settings that minimized the residuals and showed the best diagnostics outputs were used for the final assessment, and are the following:
Fishing mortality sub-model: fmodel $=$ te(age, year, $k=c(3,17))+s(a g e, k=5)$
Catchability sub-model: qmodel $=$ list( $\sim$ factor(replace(age, age $>5,5)$ ))
SR sub-model: srmod = geomean( $\mathrm{CV}=0.2$ )
Model <- sca(stock = stk, indices = idx, fmodel, qmodel, srmod)
The $n 1$ model and vmodel used in the final fit are the default ones:
n1model <- ~s(age, $k=3$ )
vmodel <- list( $\sim s(a g e, k=3), \sim 1)$

Fishing mortality

Figure 6.13.3.3. Norway lobster in GSA 9: fishing mortality by age and year obtained from the a4a model (1994-2018).

Figure 6.13.3.4. Norway lobster in GSA 9: catchability of the survey by age and year obtained from the a4a model.

The log residuals for the survey show some sign of correlation, that could be linked to the poor internal consistency of the survey data. The residuals and the fitting of the catch data are good, and are probably driving the main outcomes of the assessment.

In general, the diagnostics are considered acceptable and the a4a model is acceptable as a basis for advice.
log residuals of catch and abundance indices by age

Figure 6.13.3.5. Norway lobster in GSA 9: log residuals for the catch-at-age data of the fishery and the survey, and the catches.
log residuals of catch and abundance indices

Figure 6.13.3.6. Norway lobster in GSA 9: bubble plot of the log residuals for the catch-atage data of the fishery and the survey, and the catches.
uantile-quantile plot of log residuals of catch and abundance indice

Figure 6.13.3.7. Norway lobster in GSA 9: QQ-plot of the log residuals for the catch-at-age data of the fishery and the survey, and the catches.

Figure 6.13.3.8. Norway lobster in GSA 9: fitted vs observed values by age and year for the catches.

Figure 6.13.3.9. Norway lobster in GSA 9: fitted vs observed values by age and year for the survey.

The internal consistency of the catches is very good, while some issues are present in the survey internal consistency. The assessment is relying on the signals from the catch with only minor imput from the survey which shows small blocks of residuals across ages and years suggesting poor reslution of cohorts and correlated errors.

Cohorts consistence in the catch

Lower right panels show the Coefficient of Determination $\left(r^{2}\right)$
Figure 6.13.3.10. Norway lobster in GSA 9: internal consistency of the catch-at-age data.

## Cohorts consistence in Medits survey

$\log _{10}$ (Index Value)
Lower right panels show the Coefficient of Determination $\left(r^{2}\right)$
Figure 6.13.3.11. Norway lobster in GSA 9: internal consistency of the catch-at-age data of the MEDITS survey.

The effect of cryptic biomass was investigated, and did not show any relevant issue, as the biomass of the plus group (age 9+) is always below $5 \%$ of the total SSB, increasing to $13 \%$ in the last year.
The retrospective analysis shows that the assessment model is stable with respect to F relative to Fmsy because survey residuals show blocks with consistent possitive or negative groups its likely the assessment with exhibit section of correlated errors in SSB and F. Nevertheless the conclusion that $\mathrm{F}>\mathrm{F}_{\text {MSY }}$ is robust to all years in the retrospective. The assessment is considered acceptable for advice.

### 6.13.4 Reference Points

The STECF EWG 19-10 recommended to use $\mathrm{F}_{0.1}$ as proxy of Fmsy. The library FLBRP available in FLR was used to estimate Fo.1 $_{0}$ from the stock object resulting from the outputs of the a4a assessment.
Current $\mathrm{F}(0.31)$, estimated as the $\mathrm{F}_{\mathrm{barl} 1-3}$ in the last year of the time series, 2018) is higher than $\mathrm{F}_{0.1}(0.20)$, chosen as proxy of $\mathrm{F}_{\text {MSY }}$ and as the exploitation reference point consistent with high long-term yields, which indicates that Norway lobster in GSA 9 is over-exploited.

### 6.13.5 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the a4a stock assessment.
The input parameters for the deterministic short-term predictions (Table 6.13.5.1) were the same used for the a4a stock assessment and its results. An average of the last three years has been used for weight at age, maturity at age, while the Fbar terminal (2018) from the a4a assessment was used.

Recruitment (age 0) has been estimated from the population results as the geometric mean of the 2002-2018 (41917.9 thousand individuals), recruitment estimated for earlier years is higher and considered unsuitable to provide values for next few years .
Results of the STF are given in Table 6.13.5.2
Table 6.13.1 Norway lobster in GSA 9: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological <br> Parameters |  | mean weights at age, maturation at age, natural mortality <br> at age and selection at age, based average of 2016-2018 |
| Fages 1-3 (2019) | 0.31 | F current in the last year |
| SSB $(2019 ;$ middle <br> year $)$ | 860.4 t | Stock assessment 1 January 2019 |
| Ro $(2019$, <br> 2020,2021) | 41917.9 <br> thousands | Geometric mean of the period 2003-2018 |
| Total catch (2019) | 220.7 t | Assuming F status quo for 2019 |

Table 6.13.5.2 Norway lobster in GSA 9: short term forecast in different $F$ scenarios. SSB estimates refer to middle year.

*SSB at mid year

### 6.13.6 DATA DEFICIENCIES

Landings in 2017 were considered unreliable, as very high. Despite official data were not revised, the experts informed that a new estimation of landings was produced, and was provided to STECF 19-10.

The impact on the assessment was then low.

6.14.1. STOCK IDENTITY AND BIOLOGY

Figure 6.14.1.1. Geographical location of GSA 11

An advice on NEP in GSA 11 based on MEDITS indices trends was already given in 2018 for 2020 and can be taken directly from STECF EWG 18-12 report. STECF EWG 19-10 was asked to perform a short evaluation of survey data to determine if new data is different and could help with an assessment.

No substantial differences were found in the biological parameters.

### 6.14.2. <br> DATA

### 6.14.2.1. CATCH (LANDINGS AND dISCARDS)

Landings data were reported to STECF EWG 19-10 through the DCF. Landings data are available for GSA 11 in the period 2005-2018 and were related to OTB (Table 6.14.2.1.1, Figure 6.14.2.1.1). No discards were reported.

Length frequency distribution of the landings by year and fleet from the DCF database are presented in figure 6.14.2.1.2.

Table 6.14.2.1.1. Norway lobster landing data (in tons) in GSA 11

### 6.14.2.2. EfFORT

Fishing effort data were reported to STECF EWG 19-10 through DCF. Unexpected significant increase of OTB fishing effort has been detected in comparison with the previous years (Tables 6.14.2.2.1-3, Figures 6.14.2.2.1-3).

### 6.14.2.3. SURVEY DATA

MEDITS data are available in GSA 11 since 1994. In the period 1994-2010 MEDITS indices (Fig. 6.14.2.3.1) show highly fluctuating pattern, ranging between 1.52 (2001) and 4.46 (2009) in terms of biomass ( $\mathrm{kg} / \mathrm{Km}^{2}$ ) and 31.07 (2001) and 129.01 (2008) in terms of density ( $\mathrm{n} / \mathrm{Km}^{2}$ ), with an average value for this period of $3.01 \mathrm{~kg} / \mathrm{km}^{2}$ and $75.37 \mathrm{n} / \mathrm{Km}^{2}$. On the contrary, during the latest 8 years, density and biomass values show a more stable behaviour, oscillating respectively in the range 1.32 (2018) - 2.69 (2012) (average value 2.02) in terms of biomass and 31.53 (2018) - 58.64 (2012) (average value 45.35) in terms of density. Biomass and density average values along the whole time series was respectively $2.70 \mathrm{~kg} / \mathrm{Km}^{2}$ and $65.76 \mathrm{n} / \mathrm{Km}^{2}$.
Observed length frequency distribution for MEDITS data are reported in Figure 6.14.2.3.2 and 6.14.2.3.3.

Figure 6.14.2.3.1. MEDITS indices for the period 1994-2018: relative biomass (kg $\mathrm{km}^{2}$ ) and density ( $\mathrm{n} \mathrm{km}^{2}$ ).

Figure 6.14.2.3.2. Norway lobster in GSA 11. Observed Length-frequency distributions (MEDITS data) for males.

Figure 6.14.2.3.3. Norway lobster in GSA 11. Observed Length-frequency distributions (MEDITS data) for females.

### 6.14.3. Stock Assessment

The EWG 18-12 concluded that XSA and a4a results were considered as not acceptable due to incoherence in the landings cohorts and patterns in the residuals. $F$ values estimated by XSA and a4a were also different. EWG 18-12 decided to apply a survey-based assessment following the approach adopted by ICES for category 3 stocks.
EWG 19-10 was required to do a short evaluation of survey and landing trends to determine if new data is different and could help with an assessment. As no substantive change in survey and landing signals was observed, a new assessment has not been performed and the advice done in EWG 18-12 has been confirmed.

However, the unexpected increase in the fishing effort in the last years, could have affected the landings values of the same year, increase not detected in the survey data.

### 6.14.4. Reference Points

As the assessment carried out during EWG 18-12 was not accepted for advice, reference points were not calculated.

### 6.14.5. SHORT TERM Forecast and Catch Options

The advice on catch options for 2019 and 2020 (17.1 ton, EWG 18-12) are based on the observed catch adjusted to the change in the stock size index for the two most recent values relative to the three preceding values following the approach adopted for ICES category 3 stocks.

The analyses performed during EWG 19-10 on the biomass and density indices of the MEDITS survey confirm the decreasing trend of this resource also in 2018 in the GSA 11.
Therefore, EWG 19-10 confirms the advice given by EWG 18-12 not to exceed the catches of 17.1 tonnes for the years 2019 and 2020.

### 6.14.6. DATA DEFICIENCIES

Growth parameters previous to 2015 were available only for males, as well as length weight relationship coefficients. However, growth parameters for both sexes have been submitted since 2016.

### 6.15 BLUE AND RED SHRIMP IN GSA 1

### 6.15.1 Stock Identity and Biology

This stock was assessed last year in 2018 (STECF EWG 18-12) before that in 2015 (STECF EWG 15-18) using Extended Survivors Analysis (XSA) and prior to that in 2011 (STECF EWG 11-05) using LCA with VIT software (Lleonart and Salat, 1997).

No information was documented during regarding stock delimitation of blue and red shrimp, Aristeus antennatus (Risso, 1816). It is assumed that the stock geographical distribution corresponds to GSA 1 (Figure 6.15.1.1).

Figure 6.15.1.1. Geographical location of GSA 1.
There are some differences from 2018. The same basic growth parameters (Linf $=80 \mathrm{~mm}$ (carapace length), $K=0.37$ year $^{-1}$, $\mathrm{t}_{0}=0.032$ year) with the previous assessment for this stock in GSA 1 (STECF 15-18) were used because growth parameters were not available in the DCF dataset for blue and red shrimp in GSA 1. The starting point for the growth curve is assumed to be mid year ( $1^{\text {st }}$ July) for length slicing of length to age. In 2018 the to was intended to be as given in this way, but was in fact used as -0.032 which gave slightly different values of $n$ at age resulting is very small differences in the assessment. This year the length slicing for assessment was run with 0.532 value of $t_{0}$ in order to provide correct length transitions for $1^{\text {st }}$ of January to coincide with Jan-Dec assessment year. It should be noted that he natural mortality was calculated with $t_{0}$ set +0.032 the intented value last year.

These length equations above were calculated with modal progression analysis (Battacharya/NORMSEP), based on monthly length frequency distribution obtained from Data Collection Framework (DCF, 2014). Although females reach larger sizes compared to males, a combined set of growth parameters was used to comply with previous assessments and with the available length data, which is also combined. Length frequency distributions from the Spanish OTB fleet as well as from survey data (MEDITS) were sliced to catch-at-age, using those growth parameters with t0 set to 0.532 and age boundaries set to $1,2,3$ etc. This indicates that it is rare to catch red and blue shrimp at age zero in thje commercial catch and they are never observed in the survey.

The parameters of the length-weight relationship ( $a=0.002$ and $b=2.515$ ) were also used as in the previous assessment and had been calculated based on DCF data (DCF, 2014). The length of the sample from which growth parameters and length-weight relationship was estimated ranged between 15 and 64 mm CL.

The calculated annual individual weight at age (kg) is applied at length and sliced to age for the entire period (2002-2018) and is presented in Table 6.15.1.1.
Table 6.15.1.1. Blue and red shrimp in GSA 1. Annual individual weight (kg) at age (20022018). Based on length slicing, weight at age zero filled in with 0.001 for years with no numbers at age.

| year <br> age | 0 |  | 1 |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| 2012 | 0.0010 | 0.0089 | 0.0197 | 0.0396 | 0.0550 | 0.0730 |
| 2013 | 0.0010 | 0.0086 | 0.0197 | 0.0387 | 0.0550 | 0.0730 |
| 2014 | 0.0010 | 0.0087 | 0.0208 | 0.0388 | 0.0550 | 0.0730 |
| 2015 | 0.0010 | 0.0082 | 0.0210 | 0.0404 | 0.0550 | 0.0730 |
| 2016 | 0.0010 | 0.0083 | 0.0206 | 0.0405 | 0.0550 | 0.0730 |
| 2017 | 0.0010 | 0.0088 | 0.0203 | 0.0398 | 0.0550 | 0.0725 |
| 2018 | 0.0010 | 0.0084 | 0.0200 | 0.0383 | 0.0550 | 0.0730 |

The proportion of mature individuals at age was not available from the DCF data for blue and red shrimp in GSA 1 and in 2018 was taken from the 2015 assessment that was based on the DCF data this was applied in the 2018 assessment (Table 6.15.1.2) It noted incorrectly in the 2018 report with a one year shift, but the correct value was used in the assessment. A fixed maturity ogive is used for all years.

Table 6.15.1.2. Blue and red shrimp in GSA 1. Proportion of mature specimens (Pmat) at age.

| Age | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Pmat | 0.0 | 0.7 | 1.00 | 1.00 | 1.00 | 1.00 |

The the natural mortality of blue and red shrimp in the present assessment was calculated as a vector using the Chen Watanabe (1989) model (Table 6.15.1.3). These are calculated using the t0 $=+0.032$. Its noted that age zero natural mortality is for a full 12 months while the actual mortality is lower, only occuring in the last 6 moths of the year after spawning.

Table 6.15.1.3. Blue and red shrimp in GSA 1. Natural mortality (M) at age.

| Age | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{M}$ | 2.327 | 0.883 | 0.618 | 0.512 | 0.458 | 0.426 |

### 6.15.2 DATA

### 6.15.2.1 CATCH (LANDINGS AND DISCARDS)

## General description of Fisheries

The blue and red shrimp (Aristeus antennatus) is present in the eastern part of GSA 1 at depths ranging from 400 to 800 m . It is particularly abundant in front of Cape of Gata. The stock is exploited only by deep bottom otter trawl and particularly by the fleet segment composed by the largest trawlers (12-24 m). Around 50 vessels are targeting the blue and red shrimp in GSA 1 yielding around 100 tonnes per year. The blue and red shrimp fishery can be considered as monospecific with no significant discards (less than 0.01 tonnes per year), due to the very high price of the species. Catch is landings taken as landings with negligible discards (typically $0.02 \%$ with a max $0.3 \%$ ) reported in few years that can be safely taken as zero in all years. The SoP correction is applied and catch is used throughout this report.

Figure 6.15.2.1.1. Blue and red shrimp in GSA 1. Blue and red shrimp DCF landings (t), in GSA 1.

Table 6.15.2.1.1. Blue and red shrimp in GSA 1. Blue and red shrimp DCF landings ( t ) and discards ( t ) by OTB (all metiers) in GSA 1

| Year | OTB <br> Landings <br> (t) | OTB <br> Discards (t) |
| :---: | :---: | :---: |
| 2002 | 156.96 | - |

| 2016 | 138.22 | 0.01 |
| :---: | :---: | :---: |
| 2017 | 99.19 | 0.01 |
| 2018 | 123.21 | 0.01 |

The total OTB landings and discards per year, as reported by DCF, are shown below.

Figure 6.15.2.1.2. Blue and red shrimp in GSA 1. Blue and red shrimp DCF landings (t) in GSA 1 per gear (2002-2008) and metier (2009-2018).

Figure 6.15.2.1.3. Blue and red shrimp in GSA 1. Blue and red shrimp DCF discards ( t ) in GSA 1 per gear (2002-2008) and metier (2009-2018).

The total LFD of the landings (=catch as discards were negligible) is shown in Figure 6.15.2.1.4 and the LFD per gear and metier in Figure 6.15.2.1.5.

Figure 6.15.2.1.4. Blue and red shrimp in GSA 1. Blue and red shrimp length frequency distribution of catch (landings only) by year in GSA 1.

The variability of blue and red shrimp number of individuals ( $N$, thousands) at age of the catch by year Table 6.15.2.1.2 is shown in Figure 6.15.2.1.6 and the number of individuals ( $N$, thousands) per year by age group of the catch in Figure 6.15.2.1.7. The age composition of the catch has mainly been composed of 0-2-year-olds, with 1-year-old individuals forming the majority of catch.

| 2018 | 0.24998 | 6811.1 | 2615.7 | 349.58 | 11.253 | 1.3829 |

The calculated annual individual weight at age ( kg ) for the entire period (2002-2018) is presented in Figure 6.15.2.1.8 and the internal cohort consistency of the catch in Figure 6.15.2.1.9.

Figure 6.15.2.1.8. Blue and red shrimp in GSA 1. Blue and red shrimp mean weight (kg) at age of catches per year in GSA 1 (2002-2018). Data from DCF.

## Cohorts consistence in ARA1 catch

Figure 6.15.2.1.9. Blue and red shrimp in GSA 1. Cohorts consistency in the catch.

### 6.15.2.2 EFFORT

The fisheries for Blue and red shrimp in GSA 1 are consiodered to be 100\% OTB from Spain. However, not all OTB days at sea will be targeted at blue and red shrimp. The fishing effort expressed as number of fishing days, GTDays and Days at Sea, Fishing Days by year is presented in Figures 6.15.2.2.1, 6.15.2.2.2 and 6.15.2.2.3 respectively. All metrics are similar showing a gradual decline to 2014 and then fluctuations.

Table 6.15.2.2.1 Fishing effort expressed as number of GTDays, Days at Sea and fishing days by year for OTB from Spain in GSA1

| YEARS | GT Days | Days at <br> Sea | fishing days |

### 6.15.2.3 SURVEY DATA

### 6.15.2.3.1.Description and timing

The MEDITS survey is carried out annually from April to June (Figure 16.15.2.3.1) by the Spanish Institute of Oceanography (IEO) since 1994 at fixed haul positions. Tables TA, TB, TC were
provided according to the MEDITS protocol. Data were assigned to strata based upon the shooting position and average depth between shooting and hauling depth.

Few obvious data errors (e.g. typos, duplicated records) had been noted on the dataset (mainly regarding length frequency distributions of 2009) and were corrected prior to the analysis.

The abundance and biomass indices by GSA were calculated through stratified means. This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA.

Figure 16.15.2.3.1. Month of the year when the hauls of MEDITS survey are being conducted in GSA 1.

### 6.15.2.3.2. Geographical distribution

The blue and red shrimp are mainly concentrated at the eastern part of the north Alboran Sea and deep waters. The geographical distribution of the stock since 2002 is shown in Figure 6.15.2.3.2.

Figure 6.15.2.3.2 Geographical distribution of blue and red shrimp in GSA 1 based on the biomass index of MEDITS survey (2002-2018).

### 6.15.2.3.3 Trends in abundance and biomass

The time series of abundance and biomass indices of blue and red shrimp from MEDITS bottom trawl survey in GSA 1 are shown in the following figures (Figure 6.15.2.3.3 and 6.15.2.3.4) and table (Table 6.15.2.3.1). Both estimated abundance and biomass indices show similar trends, both maximized in 2000 and fluctuated around a mean for the last five years. The total biomass time series had been fluctuating with lower mean from 2007-2018. In two 2018 the value is similar to the mean of the later period.
Please note the very low (near zero) total biomass and density in years 2011 and 2013 were excluded from the analysis. Only four individual blue and red shrimps were caught in 2011 and 2013 probably because the hauls where the main biomass of the species is usually caught were not conducted during those years. Consequently the number of individuals at age for 2011 and

2013 from MEDITS were not used in the age based assessment, this was the same as previous years

Figure 6.15.4.3. Blue and red shrimp in GSA 1. MEDITS survey biomass index ( $\mathrm{kg} / \mathrm{km}^{2}$ ) of blue and red shrimp in GSA 1 as reported by DCF. The survey is carried out from April to June.

Figure 6.15.2.3.4. Blue and red shrimp in GSA 1. MEDITS survey abundance index ( $\mathrm{n} / \mathrm{km}^{2}$ ) of blue and red shrimp in GSA 1 as reported by DCF. The survey is carried out from April to June.

Table 6.15.2.3.1. Blue and red shrimp in GSA 1. MEDITS survey abundance index ( $\mathrm{kg} / \mathrm{km}^{2}$ ) of blue and red shrimp in GSA 1 as reported by DCF. The survey is carried out from April to June.

| Year | Blue and red shrimp abundance |
| :---: | :---: |
| 1994 | 0.686 |
| 1995 | 2.730 |
| 1996 | 1.373 |
| 1997 | 3.035 |
| 1998 | 2.225 |
| 1999 | 1.685 |
| 2000 | 7.346 |
| 2001 | 2.541 |
| 2002 | 1.913 |
| 2003 | 3.657 |
| 2004 | 1.959 |
| 2005 | 2.915 |
| 2006 | 3.245 |
| 2007 | 1.213 |
| 2008 | 0.893 |
| 2009 | 2.151 |
| 2010 | 0.793 |
| 2011 | 0.054 |
| 2012 | 1.545 |
| 2013 | 0.014 |
| 2014 | 2.067 |
| 2015 | 1.863 |
| 2016 | 2.060 |
| 2017 | 1.019 |
| 2018 | 1.541 |

Trends in abundance by length (Figure 6.15.2.3.5), the cohorts consistency in MEDITS index (Figure 6.15.2.3.6), number of individuals per year by age (Figure 6.15.2.3.7), number of individuals per age by year (Figure 6.15.2.3.8) are shown below.

Figure 6.15.2.3.5. Blue and red shrimp in GSA 1. Length frequency distribution of the MEDITS survey abundance index ( $\mathrm{n} / \mathrm{km}^{2}$ ) of blue and red shrimp in GSA 1 as reported by DCF. The survey is carried out from April to June.

Numbers at length were sliced to give numbers at age based on the same growth curves used for the catch. These were arranged to match $1^{\text {st }}$ of January birthday, by adding 0.5 to t0 as with the catch data slicing. The numbers at age are given in Table 6.15.2.3.2. The same data is and shown by year and age in Figures 6.15.2.3.6 and 6.15.2.3.7 respectively.

Table 6.15.2.3.2. Blue and red shrimp in GSA 1. Number of individuals per year by age group (ages 1-4) according to MEDITS surveys. Years 2011 and 2013 were excluded from the analysis, due to shortage of hauls in some strata in these years.

Figure 6.15.2.3.6. Blue and red shrimp in GSA 1. Age frequency distribution of the MEDITS survey of blue and red shrimp in GSA 1 as reported by DCF. The survey is carried out from April to June. Note that 2011 and 2013 were excluded from the analysis (see maintext for details).

Figure 6.15.2.3.7. Blue and red shrimp in GSA 1. Number of individuals per year by age group (ages 1-4) according to MEDITS surveys. Years 2011 and 2013 were excluded from the analysis.

### 6.15.3 Stock ASSESSMENT

This stock was assessed for the in 2018 (STECF EWG 18-12) using a4a and XSA, prior to that in 2015using XSA and 2011 (STECF EWG 11-05) using LCA with VIT software (Lleonart and Salat, 1997).

The present assessment was carried out using a statistical catch-at-age analysis (a4a) as this was the approach agreed in 2018. The same input data was used this year with the addition of 2018 catch and survey data. However different treatment of length to age that better aligns the the birthday to $1^{\text {st }}$ of January for stocks with summer spawing. This resultys in different age structure which is considered to better reflect the observed growth.

### 6.15.3.1. Input data

As decribed above the input growth parameters used were Linf $=80 \mathrm{~mm}, \mathrm{k}=0.37 \mathrm{y}^{-1}$, t0 $=-$ 0.032 y and were kept identical as in the previous assessment but 0.5 was added to $t_{0}$ for purpose of aligning sizes appropriately with $1^{\text {st }}$ of January for length slicing.

The spawning of blue and red shrimp peaks during the summer, although continuous spawning throughout the year has been reported from some areas of the Mediterranean.

The proportion of mature individuals at age was not available for blue and red shrimp in GSA 1 and was taken from the previous assessment that was based on the DCF data (Table 6.15.1.2). The maturity at age ogive was used for blue and red shrimp assessment in GSA 1 as estimated from biological sampling based on length at first maturity and growth, giving 0.7 at age 1 (spawning in the first summer).

Natural mortality (M) was estimated using Chen-Watanabe (1989) model and is shown in Table 6.15.1.3. using the origonal growth parameters (without adding 0.5 to to)

### 6.15.3.3. a4a

The Assessment for All Initiative (a4a) (Jardim et al., 2014), a4a, a statistical catch-at-age analysis method were used for this stock that utilize catch-at-age data to derive estimates of historical population size and fishing mortality. Statistical catch-at-age analysis works forward in time and the methods do not require the assumption that removals from the fishery are known without error.

## Input

Data that are typically used are: catch, abundance index, statistical sample of age composition of catch and abundance index.

Total catches and numbers at age in catches and mean weights at age in catch and stock are taken from the fishery as described above in Section 6.15.2.1.The landings data were considered as catch because discards were negligible as they are always less than $0.3 \%$ of the reported catch (Table 6.15.2.1.1).

A single tuning fleet was used based on the CPUE and weight at age estimates from summer bottom trawl surveys (MEDITS) conducted in the northern Alboran Sea (GSA 1) as reported in the DCF.Numbers at age for a tuning index are taken from MEDITS data (Section 6.15.2.3).

An assessment was performed with version 1.6 .7 of FLa4a, together with version 2.6 .13 of the FLR library (FLCore) in FLR environment. The 3.5.1 (64-bit) version of R was used.

## Settings

The analysis was carried out for the ages 0 to 4 age class (age group 4 was the plus group in the catch data and age group 3 was the true age group in the survey data) for the a4a. Concerning the Fbar, the age range used was 0-2 age groups that form the vast majority of the catch.

Different a4a models were performed (combination of different f, q, sr). The best model (according to a combination of AIC, BIC and residuals) included:
fmodel <- ~ factor(age) + factor(year)
qmodel <- list( $\sim$ s(replace (age,age $>2,2$ ), k=3))
sr: srmodel <- ~s(year)
This was the similar formulation as last year.
All diagnostic tests and retrospective analysis were applied.

## Results

The stock summary (Table 6.15.3.1, Figure 6.15.3.5) estimated N at age (Table 6.15.3.2) and F at age (Table 6.15.3.3) from the a4a assessment are provided. The diagnostics can be seen below :- the 3D contour plot (wireframe) of fishing mortality with age and year (Figure 6.15.3.6), the residuals of catch and abundance indices by age (Figure 6.15.3.7), the quantile-quantile plot of residuals (log) of catch and abundance indices (Figure 6.15.3.8), the fitted and observed catch at age (Figure 6.15.3.9) and index at age (Figure 6.15.3.10), the residuals of catch and abundance index (Figure 6.15.3.11) as well as the retrospective analysis (Figure 6.15.3.12) and the stock summary of the simulated and fitted data (Figure 6.15.3.13).

## Historical stock trends

## Spawning stock biomass (SSB)

The SSB shows a clear decreasing trend since 2012 but appear rather stable in the last three years. The average SSB in the last 5 years of the dataset (2014-2018) is 106 t , which is considerably lower compared to the average SSB in the beginning of the time series (2002-2006) that was 136 t (Figure 6.15.3.5).

## Recruitment

Recruitment shows similar declining pattern since 2005 (highest value in the time series). The recruitment in 2018 was 250,000 individuals, near the mean of the time series(Figure 6.15.3.5). The overall average recruitment that was used in the STF was 270298 recruits.

## Catch

Catch declined from around 250 t in 2002-2004 to around 100 t in 2018, with a clear declining trend since 2014. It appeared rather stable from 2008 to 2014.

Fishing mortality (F)
$F$ has been exceeding $F_{0.1}$ since 2003. It declined in the early part of the time-series but has fluctuated around 1.0 until 2017 but has increased again in the last year to 1.14.

Figure 6.15.3.5. Blue and red shrimp in GSA 1. Stock summary for blue and red shrimp in GSA 1, recruits, SSB (Stock Spawning Biomass), catch and harvest (fishing mortality).

Figure 6.15.3.13. Blue and red shrimp in GSA 1. Stock summary of the simulated and fitted data from a4a.

The assessment this year is different from last year in two ways, the data has been treated differently in the length slicing in order to obtain good alignment with the perception of intividal growth at the time of the survey, and size at $1^{\text {st }}$ of January. In order to slice the catch and survey at length the positioning of the length at $1^{\text {st }}$ of January takes into account the growth at to best optimes this with: the spawing period of mid year the size at maturity ( $\sim 24 \mathrm{~mm}$ ) and a calendar year for the assessment. In order to test if this change was having an important difference in the perception of the state of the stock, last years assessment, this years assessment and an asessment carried out with this years data sliced using the parameters of last year are compared below. It can be seen that $F / F_{M S Y}$ in 2017 and 2018 are highly comparable across data treatments. As the new method has greater biological realism this is the method chosen and reported in detail above.

| Method F01 | F01 | Fbar <br> $\mathbf{2 0 1 7}$ | F01/ <br> Fbar2017 | Fbar <br> $\mathbf{2 0 1 8}$ | F/FMSY <br> $\mathbf{2 0 1 8}$ |

### 6.15.4 Reference Points

The stock of blue and red shrimp in GSA 1 was assessed using the statistical catch-at-age method (a4a) that was applied to catch data for the period 2002-2018 and tuned with MEDITS survey data.

### 6.15.4.1. Methods

The FLBRP package allowed a Yield per recruit analysis and an estimate of some F-based Reference Points as Fmax and Fo.1. In all cases biological and parameters, $F$ and Ms were taken as mean of last three years.

The reference points $F_{0.1}$ is estimated as 0.56 for $F$ ages $1-2$
The fishing mortality rate corresponding to $\mathrm{F}_{0.1}$ is considered by STECF as a proxy of $\mathrm{F}_{\text {MSY }}$.

### 6.15.5 Short term Forecast and Catch Options

### 6.15.5.1. Method

A deterministic short term prediction for the period 2015 to 2017 was performed using the FLR routines provided by JRC and based on the results of the XSA stock assessments performed during EWG 15-11.

### 6.15.5.2. Input parameters

The same input parameters of the a4a model and the model output were used for running the
short term forecast. The intermediate year assumptions are given in Table 6.15.5.1. The $F$ status quo is estimated as mean for last three years $F=1.13$ as $F$ is seen to fluctuate. No trend in recruitment is observed so R 2019 is taken as geometric mean of time series.

Table 6.15.5.1 Blue and red shrimp in GSAs 1: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological <br> Parameters |  | mean weights at age, maturation at age, natural mortality <br> at age and selection at age, based average of 2016-2018 |
| Fages 1-2 (2019) | 1.13 | mean F 2016-2018 is used to give F status quo for 2019 |
| SSB (2019) | 106.3 | Stock assessment 1 January 2019 |
| Rageo (2019,2020) | 259960 | Geometric mean of the last 17 years (full time series) |
| Total catch (2019) | 139.6 | Assuming F status quo for 2019 |

## Table 6.15.5.2. Results of STF

The results of the short term forecasts for blue and red shrimp (GSA 1) are shown in table 6.15.5.1.

### 6.15.6 DATA DEFICIENCIES

There were issues with the dataset regarding the survey index for 2009 that were identified before the meeting. These issues (reporting of a very large individual with CL=362 mm and duplicate records for some length classes) were resolved before the index was prepared for running the assessment.

### 6.16.1 Stock Identity and Biology

GSA 5 (Figure 6.16.1) has been pointed as an individualized area for assessment and management purposes in the western Mediterranean (Quetglas et al., 2012) due to its main specificities. These include: 1) Geomorphologically, the Balearic Islands (GSA 5) are clearly separated from the Iberian Peninsula (GSA 6) by depths between 800 and 2000 m, which would constitute a natural barrier to the interchange of adult stages of demersal resources; 2) Physical geographically-related characteristics, such as the lack of terrigenous inputs from rivers and submarine canyons in GSA 5 compared to GSA 6, give rise to differences in the structure and composition of the trawling grounds and hence in the benthic assemblages; 3) Owing to these physical differences, the faunistic assemblages exploited by trawl fisheries differ between GSA 5 and GSA 6, resulting in large differences in the relative importance of the main commercial species; 4) There are no important or general interactions between the demersal fishing fleets in the two areas, with only local cases of vessels targeting red shrimp in GSA 5 but landing their catches in GSA 6; 5) Trawl fishing exploitation in GSA 5 is much lower than in GSA 6; the density of trawlers around the Balearic Islands is one order of magnitude lower than in adjacent waters; and GSA 6. Due to this lower fishing exploitation, the demersal resources and ecosystems in GSA 5 are in a healthier state than in GSA 6, which is reflected in the population structure of the main commercial species (populations from the Balearic Islands have larger modal sizes and lower percentages of small-sized individuals), and in the higher abundance and diversity of elasmobranch assemblages.

Figure 6.16.1 Geographical location of GSA 5.

The reproductive period for the blue and red shrimp in GSA 5 began in May and ended in September. Two main peaks were detected as an entry of juveniles (recruits) to the fishery: one in February-March and the other in September-October, for both females and males (Carbonell et al., 1999). For females, condition index, hepatosomatic index and the content of lipids in the
hepatopancreas showed the minimum values at the end of the spawning period (Guijarro et al., 2008).

### 6.16.2 DATA

## General description of the fisheries

In the Balearic Islands, commercial trawlers develop up to four different fishing tactics, which are associated with the shallow shelf (SS), deep shelf (DS), upper slope (US) and middle slope (MS) (Guijarro and Massutí 2006; Ordines et al. 2006), mainly targeted to: (i) Spicara smaris, Mullus surmuletus, Octopus vulgaris and a mixed fish category on the SS ( $50-80 \mathrm{~m}$ ); (ii) Merluccius merluccius, Mullus spp., Zeus faber and a mixed fish category on the DS (80-250 m); (iii) Nephrops norvegicus, but with an important by-catch of big M. merluccius, Lepidorhombus spp., Lophius spp. and Micromesistius poutassou on the US (350-600 m) and (iv) Aristeus antennatus on the MS (600-750 m). The MS fishing tactics coincides with the metier OTB_DWSP; OTB_DEMSP corresponds to those days in one of the other fishing tactics is present (SS, DS and/or US) and OTB_MDDWSP corresponds to those days in which one haul in MS and at least one of the other fishing tactics is performed.

### 6.16.2.1 CATCH (LANDINGS AND DISCARDS)

## Landings

Landings data were reported to STECF EWG 19-10 through the Data call. They come exclusively from bottom trawl, both from OTB_DWSP and OTB_MDDWSP (Figure 6.16.2.1). From the period in which information by metier was available (2009-2017), the relative importance of OTB_DWSP oscillates between 30 and $73 \%$.

Figure 6.16.2.1 Blue and red shrimp in GSA 5. Blue and red shrimp DCF landings ( t ) in GSA 5 by gear (2002-2008)

Table 6.16.2.1 Blue and red shrimp in GSA 5. Blue and red shrimp DCF landings ( t ) in GSA 5 by gear (2002-2008)

| Year | OTB-1 | OTB_MOD |
| :--- | :--- | ---: |
| 2002 |  | OTB_DWS |
| 2003 |  | 141.45 |
| 2004 |  | 122.01 |
| 2005 |  | 193.58 |
| 2006 |  | 191.48 |
| 2007 |  | 213.89 |
| 2008 |  | 239.12 |
| 2009 |  | 232.85 |
| 2010 |  | 126.16 |
| 2011 |  | 153.24 |
| 2012 |  | 111.24 |
| 2013 |  | 201.14 |
| 2014 |  | 188.6 |
| 2015 |  | 141.28 |
| 2016 |  | 160.15 |
| 2017 |  | 138.1 |
| 2018 |  | 171.35 |
|  |  | 249.68 |

## Discards

Landings data were reported to STECF EWG 19-10 through the Data call. The percentage of the catch discarded for the blue and red shrimp in GSA 5 is very low, generally lower than $1 \%$ and thus they can be considered as nil and were not included in the assessment.

### 6.16.2.2 EfFORT

Effort data were reported to STECF EWG 19-10 through the Data call. The parameters showed a clear decreasing trend for the period analysed.

Figure 6.16.2.2 Blue and red shrimp in GSA 5. Effort data (days at sea) of OTB in GSA 5 as reported by DCF.

### 6.16.2.3 SURVEY DATA

The MEDITS (MEDiterranean International Trawl Survey) survey is an extensive trawls survey occurring in all European countries and included in the Data Collection Framework. According to the MEDITS protocol (Bertrand et al., 2002), it takes places every year during springtime following a random stratified sampling by depth (5 strata: 0-50 m, 50-100 m, 100-200 m, 200500 m and over 500 m ). The number of hauls in each stratum is proportional to the surface of the stratum and their positions were randomly selected and maintain fixed throughout the time. Same sampling gear (GOC73), characterized by a 20 mm stretched mesh size cod-end, is used throughout GSAs and years.

The Balearic Islands were only partially covered by the MEDITS survey during 1994-2006, with a very low number of surveys by year, covering only a small part of the area (Ibiza channel). Thus, only the information collected from 2007 on, when the sampling was extended, should be considered in stock assessment (Figure 6.16.2.3 and Table 6.16.2.2).

Figure 6.16.2.3 Blue and red shrimp - GSA 5. Biomass ( $\mathrm{kg} / \mathrm{km}^{2}$ ) and density ( $\mathrm{n} / \mathrm{km}^{2}$ ) indices from the MEDITS survey.

### 6.16.3 Stock ASSESSMENT

The EWG 18-12 concluded both neither the XSA nor a4a assessment provided stable models suitable for advice. In the absence of an assessment the EWG 18-12 decided to apply a surveybased assessment following the approach adopted by ICES for category 3 stocks.

EWG 19-10 was required to do a short evaluation of survey and landing trends to determine if new data is different and could help with an assessment. As no substantive change in survey and landing data in 2018 was observed, a new assessment has not been performed and the advice done in EWG 18-12 has been confirmed by the EWG 19-10.

### 6.16.4 Reference Points

The assessment carried out by the EWG 18-12 has not been accepted, therefore reference points were not calculated.

### 6.16.5 Short term Forecast and Catch Options

The advice on catch option for 2019 (150 tonnes, EWG 18-12) was based on the observed catch adjusted to the change in the stock size index for the two most recent values relative to the three preceding values following the approach adopted for ICES category 3 stocks.
The review of the biomass and density indices of the MEDITS survey by the EWG 19-10, confirms the observed trend, and therefore the EWG 19-10 reiterrates the advice from the previous year, to not exceed the catches of 150 tonnes for the years 2019 and 2020.

### 6.17 BLUE AND RED SHRIMP IN GSA 6 AND 7

### 6.17.1 Stock Identity and Biology

This stock was assessed for the last time in 2018 (STECF EWG 18-12) using XSA and a4a.
No information was documented regarding stock delimitation of blue and red shrimp, Aristeus antennatus (Risso, 1816). It is assumed that the stock geographical distribution corresponds to GSA 6\&7 (Figure 6.17.1.1).

Figure 6.17.1.1. Geographical location of GSA 6\&7.

The growth parameters used were taken from Garcia-Rodriguez (2003), just as in the previous assessment (STECF EWG 18-12); these are estimated from length frequency distributions analysis (Linf $=77.0 \mathrm{~mm}$ (carapace length); $K=0.38$ year $^{-1} ; \mathrm{t} 0=-0.065$ year).
This species shows sexual dimorphism, as females reach larger sizes compared to males, but only a combined set of growth parameters was available, and catch length data available were combined as well. Therefore, length frequency distributions from the Spanish OTB fleet as well as from survey data (MEDITS) were sliced to catch-at-age, using combined growth parameters.

The parameters of the length-weight relationship were taken from DCF data call 2017 ( $a=$ $0.0020 ; \mathrm{b}=2.5120$ ) and corresponded to the ones used in the previous assessment (STECF EWG 18-12).
The proportion of mature individuals at length was available from the DCF for blue and red shrimp in GSA 6\&7 (Table 6.17.1.2).

Table 6.17.1.1. Blue and red shrimp in GSA 6\&7. Proportion of mature specimens (Pmat) at age.

| Age | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Pmat | 0.07863 | 0.7669 | 0.998 | 1 | 1 | 1 |

The natural mortality of blue and red shrimp in the present assessment was calculated as a vector using the Chen and Watanabe (1989) equation (Table 6.17.1.3).

Table 6.17.1.2. Blue and red shrimp in GSA 6\&7. Natural mortality (M) at age.

| Age | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 6.17.2 DATA

### 6.17.2.1 CATCH (LANDINGS AND DISCARDS)

## General description of Fisheries

Blue and red shrimp is one of the most important crustacean species in catches and value of GSAs 6\&7. It is a deepwater species caught exclusively by bottom trawl. The blue and red shrimp has a wide bathymetric distribution, between 80 and 3300 m depth (Sardà et al., 2004), although commercial fishing grounds are located between 450 and 900 m depth. Deeper areas may act as a refuge for the stock, specially for the juvenile fraction, as they are located far from the main fishing ports and below 1000 m of depth where the trawl fishing is banned (GFCM resolution $2005 / 1$ ). Females predominate in the landings, representing nearly $80 \%$ of the total landings. Discards of the blue and red shrimp are practically nil because of the high commercial value of the species. Other accompanying species of commercial value in the catches are large individuals of hake, greater forkbeard, Nephrops and blue whiting. Exploitation is based on young age classes, mainly 1 and 2 year old individuals. The discarded component of the catch is small (Table 6.17.2.1), therefore catch and landings are considered as equal and the term catch will be used throughout this report. The total LFD of the landings (=catch as discards were negligible) is shown in Figure 6.17.2.4.

Figure 6.17.2.1. Blue and red shrimp in GSA 6\&7. Blue and red shrimp DCF total catch ( t ), in GSA 6\&7.

### 6.17.2.2 EFFORT

Blue and red shrimp in GSA 6\&7 is exploited only by bottom trawlers. Effort data are available from 2004 to 2008 as combined data from bottom trawling gears, while from 2009 to 2018 the data are reported as single fishery types. Fishing effort is presented in Figure 6.17.2.2.1 and in

Table 6.17.2.2.1. The lack of FRA effort data for the period before 2015 were noticed before (see and France was requested to provide missing data, but these data was not submitted and thus not available to EWG19-10.

### 6.17.2.3 SURVEY DATA

### 6.17.2.3.1 Description and timing

The MEDITS surveys are carried mainly from May to July (Figure 16.17.2.3.1). Tables TA, TB, TC were provided according to the MEDITS protocol. Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors (e.g. typos, duplicated records) had been noted (MEDITS issues 2009) and were corrected prior to the analysis.

The abundance and biomass indices for GSA 6\&7 were calculated through stratified means. This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas.

Figure 16.17.2.3.1. Month of the year when the hauls of MEDITS survey are being conducted in GSA 6\&7.

### 6.17.2.3.2 Geographical distribution

The blue and red shrimp are mainly concentrated in the northern and southern parts of the region, while it is not present in the centre of the Spanish area where waters are shallower. The distribution did not show substantial variation across time (Figure 6.17.2.3.2).

Figure 6.17.2.3.2. Geographical distribution of blue and red shrimp in GSA 6\&7 based on the biomass index of MEDITS survey every 10 years and in 2018.

### 6.17.2.3.3 Trends in abundance and biomass

The time series of abundance and biomass indices of blue and red shrimp from MEDITS bottom trawl survey in GSAs $6 \& 7$ are available since 1994 as shown in the Figures 6.17.2.3.3.1 and 6.17.2.3.3.2, and Table 6.17.2.3.3. Both estimated abundance and biomass indices show similar trends as both declined consistently from 2012 onwards, and showing a quite variable trend before 2012. The trends in abundance by length are shown on Figure 6.17.2.3.3.3.

Figure 6.17.2.3.3.1 Blue and red shrimp in GSA 6\&7. MEDITS survey abundance index ( $\mathrm{n} / \mathrm{km}^{2}$ ) of blue and red shrimp in GSA 6\&7 as reported by DCF.

### 6.17.3 Stock ASSESSMENT

This stock was assessed for the last time in 2018 (STECF EWG 18-12) using XSA and a4a. The present assessment was carried out using a statistical catch-at-age modeling framework Assessment for all (a4a, Jardim et al., 2014) in FLR (http://www.flr-project.org/).

When slicing length to age for stocks with mid year spawning and January to December assessmemnt year it is necessary to ensure that growth to January (calendar year boundary) and growth to July (12 months of growth) are coherent with the slicing process (see Section 3). The slicing routine assigns age 0 to ages from 0 to 0.99 and age 1 to 1 to 1.99 . If growth is defined on a birth date mid year and the assessment is from Januay to December then slicing needs to occur at age 0 from 000.49 and age 1 from 0.5 to 1.5 , this is arranged by adding 0.5 to to. When processing length frequency data here, the two aproaches were applied to length to age slicing both catch and survey data: with/without adding 0.5 years to $t_{0}$ (see Section 6.17.3.2 and section 6.17.3.3, to be called from now on " $\mathrm{t}_{0}$ ", and " $\mathrm{t}_{0}+0.5$ " approaches, respectively). This was necessary because without 0.5 there were large numbers of age 0 in both catch and particularly survey which are not expected and some unusual patterns in catch errors emerging when using the "t $t_{0}+0.5$ " approach. Further on, two data sets, and respectively two sets of results were considered by the group.

### 6.17.3.1. Input data

The growth parameters used to slice length frequency data from both, commercial and survey data, were Linf $=77 \mathrm{~mm}, \mathrm{k}=0.38 \mathrm{y}^{-1}, \mathrm{t} 0=-0.065 \mathrm{y}$, the same as in the previous assessment.

The spawning of blue and red shrimp peaks during the summer, although continuous spawning throughout the year has been reported from some areas of the Mediterranean. Natural mortality (M) at age was estimated using the Chen-Watanabe (1989) model. Proportion of mature and M at age are shown in Tables 6.17.1.1 and 6.17.1.2.

The landings were considered as equal to catches because discards were negligible as they are usually less than $1 \%$ of the reported catch (Table 6.17.2.1). The MEDITS bottom trawl survey data (Table 6.17.2.3.3) were used for tunning of the a4a models.

### 6.17.3.2 Stock assessment using data processed according the "t0 approach"

Inbut data in terms of catch numbers and mean weight at age, and tuning data in terms of catch numbers from the MEDITS survey are shown in Figure 6.17.3.2.1 to Figure 6.17.3.2.5. It can be noted that there are considerable numbers of age 0 (young of the year) individuals especialy in the catches obtained when the standard parameters of the VBGF are used for slicing of the LFD data (so called "t0 approach").

The cohort consistency in the catch and survey data are shown on Fig. 6.17.3.2.6 . Quite low consistency between cohorts is observed in survey data.

The plus group in the catch data was set to age 4 , and ages $0-3$ were used to tune the assessement model. The age range of Fbar was set to $0-2$ as the majority of the catches were represented within these age classes.

Different a4a models were tested and the best model (according to model diagnostcs) included the following submodels:

## A4a submodels:

Fishing mortaliy: fmodel <- ~ s(year, k=6) + factor(replace(age,age>3,3))
Survey catchability: qmodel <- list(~s(replace(age,age>2,2), k=3,by=breakpts(year,c(2004))))
Stock-recruit: srmodel <- ~ geomean(CV=0.2)
Variance model: vmodel <- list( $\sim s($ age, $k=3), \sim s($ age, $k=3))$
Summary results and diagnostics from the a4a model are presented in Figure 6.17.3.2.8 to Figure 6.17.3.2.12.

The residuals show some more pronounced year effects in 2008 when the estimated catch is lower that the observed (Figs. 6.17.3.2.8, 6.17.3.2.9, 6.17.3.2.11). The fit to the catch numbers looks much better than the fit to survey data (Fig. 6.17.3.2.9). The retrospective analysis shows moderate tendency to underestimate the fishing mortality and overestimate SSB (Figure 6.17.3.2.10). The estimated catch follows closely the main pattern in observed catches except for 2008 (Figure 6.17.3.2.11).

The stock summary with simulated confidence intervals is presented at Figure 6.17.3.2.12. The recrutment has an increasing trend until 2014, then decreased. Similarly the SSB decreased and Fbar increased after 2015.

### 6.17.3.3 Stock assessment using data processed according the "t0 +0.5 approach"

Inbut data in terms of catch numbers and mean weight at age, and tuning data in terms of catch numbers from the MEDITS survey are shown in Figure 6.17.3.3.1 to Figure 6.17.3.3.5. Unlike the previous assessment (Section. 6.17.3.2), it is to note the lack of age 0 (young of the year) individuals in the catches and survey due to the application of the "t $0+0.5$ approach").

The cohort consistency in the catch and survey data are shown in Fig. 6.17.3.3.6 . Low consistency between cohorts is observed in survey data, except between ages $3 \& 4$.

The plus group in the catch data was set to age 5, and ages 1-4 were used to tune the assessement model. The age range of Fbar was set to $1-2$ as the majority of the catches were represented within these age classes.

Different a4a models were tested and the best model (according to model diagnostcs) included the following submodels:

## A4a submodels:

Fishing mortaliy: fmodel <- ~ s(year, k=7) + factor(replace(age,age>2,2))
Survey catchability: qmodel <- list(~s(replace(age,age>3,3), k=3, by=breakpts(year,c(2004))))
Variance model: vmodel<- ist( $\sim s(a g e, k=3), \sim s(a g e, k=3))$
Stock-recruit: srmodel <- ~ geomean(CV=0.25)
Summary results and diagnostics from the a4a model are presented in Figure 6.17.3.3.8 to Figure 6.17.3.3.12.

The 3D plot of fishing mortality at age (Fig. 6.17.3.3.7) reflects the assumption of constant F after age 2. The residuals show major year effects in 2008 and 2011 when the estimated catch (Figs. 6.17.3.3.8, 6.17.3.3.9, 6.17.3.3.11). The fit to the catch numbers show major discrepencies in several years (Fig. 6.17.3.3.9). The estimated catch looks somehow out of phase
with the observed catches (Figure 6.17.3.3.11).The retrospective analysis shows moderate tendency to underestimate the fishing mortality and overestimate SSB (Figure 6.17.3.3.10).

The stock summary with simulated confidence intervals is presented at Figure 6.17.3.3.12. The recrutment has an increasing trend until 2010, then decreased. Similarly the SSB increased until 2010 then decreased. Fbar decreased from 2011 to 2015, then slightly increased. Therefore, the trends in abundance, biomass and fishing mortality in this assessment show some differences from the assessment following the "to approach".

| 2018 | 697470 | 402.57 | 1.29 | 643.50 |

## Summary of the two assessments

The pros and cons of the two approaches of slicing LFD data, and respective assessment are summarised bellow:

The "to approach" pros: more regular fit to catch data, cons: large amount of age 0 individuals in the catches

The "to +0.5 approach" pros: no age 0 individuals in the catches, cons: larger missmach between estimated and observed catch (seems out of phase).

Finally, the EWG prefered the second assessment (Ch. 6.17.3.2 "to +0.5 approach"), because it is in line with the conceptual model of slicing LFD of summer spawning fishes described in Section. 3.2. The following estimation of reference points and short term forecasts, are carried out using output of second assessment (according to the "to +0.5 approach"). The EWG catch advice is given in section 5.17 is based on the second assessment with length slicing with 0.5 added.

### 6.17.4 Reference Points

The STECF EWG 19-10 recommended to use Fo.1 as proxy of Fmsy. The library FLBRP available in FLR was used to estimate $\mathrm{F}_{0.1}$ from the stock object resulting from the outputs of the a4a assessment according to the "to +0.5 approach" (Section. 6.17.3.3). Current F (1.26, estimated as the Fbar 1-2 in the last year of the time series, 2017) is higher than $\mathrm{F}_{0.1}(0.33)$, chosen as proxy of $\mathrm{F}_{\mathrm{MSY}}$ and as the exploitation reference point consistent with high long-term yields, which indicates that blue and red shrimp stock in GSAs 6 is over-exploited.

### 6.17.5 Short term Forecast and Catch Options

### 6.17.5.1 Method

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the a4a stock assessment according to the "to +0.5 approach" (Ch. 6.17.3.2).

Table 6.17.5.1 Blue and red shrimp in GSAs 6 \& 7: Assumptions made for the interim year and in the STF forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological <br> Parameters |  | mean weights at age, maturation at age, natural mortality <br> at age and selection at age, based average of 2016-2018 |
| Fages 1-2 (2019) | 1.26 | F2019 status quo is mean Fbar 2016-2018 |
| SSB (2019) | 392 | SSB from assessment |
| Rageo (2019) | 387906 | Geometric mean of R from time series years 2012 to 2018 |
| Total catch (2019) | 600 t | Catch at F status quo in 2019 |

### 6.17.5.2 Results

The results of the short term forecasts for blue and red shrimp (GSA 6\&7) are shown in Fig. 6.17.5.1. and Table 6.17.5.1.

The current Fbar (1.26), which corresponds to average Fbar over 2016-2018, is larger than Fo.1 (0.33), which is a proxy of Fmsy and is used as the exploitation reference point consistent with high long term yields. This indicates that blue and red shrimp in GSA 6\&7 is over exploited. The catch of blue and red shrimp in 2020, consistent with $\mathrm{F}_{0.1}$ ( 0.33 ), should not exceed 226 tonnes, $65 \%$ less than the current estimated catch (644 t).

Figure 6.17.5.1 Annual catch scenarios and predictions of catch and SSB for blue and red shrimp (GSA 6\&7).

Table 6.17.5.1 Blue and red shrimp (ARA) in GSA $6 \& 7$ short term forecast. Annual catch scenarios and predictions of catch and SSB. All weights are in tonnes. Basis: F (status quo) $=$ geometric mean of F 2016-F 2018 = 1.26, Catch (2019) $=600 \mathrm{t}$, Recruitement= geometric mean of Recruits 2012-F 2018.

### 6.17.6 Data Deficiencies

Considering that blue and red shrimp shows sex dimorphism, females grow more than males, the lack of growth information on both sexes, instead of combined parameters, could potentially bias the slicing procedure.

### 6.18 BLUE AND RED SHRIMP IN GSA 9, 10 \& 11

### 6.18.1 Stock Identity and Biology

The assessment of Blue and red shrimp carried out during the STECF EWG 19-10 considered the stock shared by the GSAs 9, 10 and 11.

Figure 6.18.1.1. Geographical location of GSAs 9, 10 and 11 .

The growth of A. antennatus has been studied both in the southern part than in the northern part of the GSA9 using model progression analysis (Colloca et al., 1998, Orsi Relini and Relini, 1998). Data on recruitment from the Ligurian Sea (Orsi Relini and Relini, 1998) and results of tagging studies (Relini M. et al., 2000, 2004) provided the basis for an interpretation of growth in which the possible life span of $A$. antennatus was of $8-10$ years. The following sets of Von Bertalanffy growth parameters were estimated:
Females: $\mathrm{L} \infty=76.9, \mathrm{~K}=0.21, \mathrm{t} 0=-0.02$ and
Males: $\mathrm{L} \infty=46, \mathrm{~K}=0.21, \mathrm{t} 0=-0.02$ (Orsi Relini and Relini, 1998).
More recently this interpretation of growth has been confirmed (Orsi Relini and Mannini, 2011; Orsi Relini et al., 2013).
STECF EWG 19-10 used the above set of growth parameters to convert catch in length into age (Figure 6.18.1.2).
LW relationship parameters by GSA were very similar. As input for the assessment the median values of $a$ and $b$ from GSA9 (Figure 6.18.1.3) were used.
The VBGF and LW relationship parameters used are summarized in the following Table (Tab. 6.18.1.1). The reproduction period, although with some differences between the various geographic areas of the Mediterranean, is somewhat extended, starting in spring (April), peaking in summer (July-August), when most of the females reach sexual maturity, and ending in autumn (October-November) (Orsi Relini and Relini, 1979; Orsi Relini and Pestarino, 1981; Colloca et al., 1998). Based on this, the proportions of $F$ and $M$ before spawning were set to 0.5 in the assessment model

### 6.18.2 DATA

### 6.18.2.1 CATCH (LANDINGS AND DISCARDS)

The blue and red shrimp is one of the most important target species of the fishery carried out on the muddy bottoms of the upper and middle slope. The species is almost exclusively exploited with otter bottom trawling. In the past, in particular in the GSA10 there was a Gillnet fleet (GNS) targeting ARA associated with very low landings (less than 1.5 t ). Sporadic landings are reported for FPO, GTR and OTM.

## Landings

Landings data were reported to STECF EWG 19-10 through the DCF. Landings data by year and fleet are presented in Figure 6.18.2.1.1, total landings by year are presented in Table 6.18.2.1.1. Landings for GSA10 and 11 were revised according FDI data.

shrimp in GSAs 9, 10 and 11. Length by year and fleet.

## Discards

Blue and red shrimp is very rarely discarded. Anyway some data were reported to STECF EWG $19-10$ through the DCF for GSA9 in 2011 ( 0.40 tonnes) and included in the stock assessment. Total discard by year for the bottom trawl fishery is presented in Table 6.18.2.1.2.

Table 6.18.2.1.2. Blue and red shrimp in GSAs 9, 10 and 11. OTB discards data in tons by GSA.

### 6.18.2.3 SURVEY DATA

The MEDITS (Mediterranean International Trawl Survey) survey is an extensive trawl survey occurring in all European countries and included in the Data Collection Framework. According to the MEDITS protocol (Bertrand et al., 2002), it takes places every year during springtime, following a random stratified sampling by depth (5 strata: 0-50 m, 50-100 m, 100-200 m, 200500 m and over 500 m ). The number of hauls in each stratum is proportional to the surface of the stratum and their positions were randomly selected and maintained fixed throughout the time. Same sampling gear (GOC73), characterized by a 20 mm stretched mesh size cod-end, is used throughout GSAs and years.
In the current assessment, combined MEDITS data for GSAs 9, 10 and 11 from 2006 onwards were used, as commercial data were fully available for the three GSAs starting from that year. The combined MEDITS indexes were calculated using the script provided by JRC (Figures 6.18.2.3.1 and 6.18.2.3.2).

Figure 6.18.2.3.1. Blue and red shrimp in GSAs 9, 10 and 11. Estimated biomass indices from the MEDITS survey $\left(\mathrm{kg} / \mathrm{km}^{2}\right)$.

Figure 6.18.2.3.2. Blue and red shrimp in GSAs 9, 10 and 11. Estimated density indices from the MEDITS survey ( $\mathrm{n} / \mathrm{km}^{2}$ ).

Both estimated abundance and biomass indices show similar trends, with strong fluctuations throughout the time series.
Size structure indices are shown in Figure 6.18.2.3.3.

Figure 6.18.2.3.3. Blue and red shrimp in GSAs 9, 10 and 11. Length frequency distribution by year and sex of MEDITS survey.

### 6.18.3 STOCK ASSESSMENT

A statistical catch-at-age assessment was carried out for this stock, using the Assessment for All Initiative (a4a) method (Jardim et al., 2015). The a4a method utilizes catch-at-age data to derive estimates of historical population size and fishing mortality. However, unlike XSA, model parameters estimated using catch-at-age analysis are done so by working forward in time and analyses do not require the assumption that removals from the fishery are known without error.
The assessment was carried out using the period 2006-2018 for catch data and tuning file for which data were fully available in the three GSA ( 2005 distribution from GSA11 was clearly affected by under sampling procedures (abundance ranged across few length classes) and so was decided to skip this year). Both catch numbers at length and index number at length were sliced using the a4a age slicing routine in FLR, using for each GSA the corresponding growth parameters by sex. Catch at age by sex were obtained splitting commercial total length distribution according to a sex-ratio vector model obtained from DCF available sex ratio vectors in the areas. The analyses were carried out for the ages 1 to $6+$. Concerning the Fbar, the age range used was 2-5 age groups.

## Input data

The growth parameters used for VBGF were the one reported in table 6.18.1.1.
Total catches and catch numbers at age from the single GSAs were used as input data. SOP correction was applied to catch numbers at age (Table 6.18.3.1). High SOP correction values in the last year in GSA10 and GSA11 are due to missing reporting abundance data by quarter (GSA10) and no sampling data for DWS (GSA11) for which, even though not selected in the ranking system, landings reported were substantial. Thus SoP for those years reflects data late and missing reporting and not errors in the data.

Table 6.18.3.1. Blue and red shrimp in GSAs 9,10 and 11. SOP correction vector.

|  | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 | 2016 | 2017 | 2018 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Assessment results

Different a4a models were performed (combination of different $f$ and $q$ ). The best model (according to residuals and retrospective) included:

## a4a model fit for: ARA91011

## Submodels:

fmodel: ~s(age, $k=5)+s(y e a r, k=5)$
srmodel: ~factor(year)
n1model: ~s(age, k=3)
qmodel:
IND: ~factor(replace(age, age > 4, 4))
vmodel:
catch: ~s(age, $k=3$ )
IND: ~1

Results are shown in Figures 6.18.3.5-6.18.3.11.

Figure 6.18.3.5. Blue and red shrimp in GSAs 9, 10 and 11. Stock summary from the final a4a model.

## Retrospective

The retrospective analysis was applied up to 2 years back. Models results were quite stable (Figure 6.18.3.10).

Figure 6.18.3.10. Blue and red shrimp in GSAs 9, 10 and 11. Retrospective analysis.

## Simulations

In the following figures and tables, the population estimates obtained by the a4a model are provided.

Figure 6.18.3.11. Blue and red shrimp in GSAs 9,10 and 11 . Stock summary of the simulated and fitted data for the a4a model.

| 2018 | 0.06 | 0.56 | 1.23 | 1.75 | 2.25 | 1.15 |

Based on the a4a results, the Blue and red shrimp SSB shows a fluctuating pattern reaching the lowest value in 2018 ( 353 tonnes). The number of recruits a fluctuating pattern until a minimum value reached in 2018 (21035). Fbar (2-5) shows a fluctuating pattern with a steep increase in the last years (Fbar $2019=1.45$ ).

### 6.18.4 Reference Points

The time series is too short to give stock recruitment relationship, so reference points are based on equilibrium methods. The STECF EWG $19-10$ recommended to use $F_{0.1}$ as proxy of FMSy. The library FLBRP available in FLR was used to estimate $F_{0.1}$ from the stock object resulting from the outputs of the a4a assessment.
Current $F$ (1.45, estimated as the $F_{b a r 2-5}$ in the last year of the time series, 2018) is higher than $\mathrm{F}_{0.1}(0.39)$, chosen as proxy of $\mathrm{F}_{\mathrm{MSY}}$ and as the exploitation reference point consistent with high long-term yields, which indicates that Blue and red shrimp stock in GSAs 9, 10 and 11 is high overfishing.

In Figures 6.18.4.1 Yield per Recruit model and histogram of the probabilities of $\mathrm{F}_{0.1}$, Fbar and F/ FMSY according to 500 simulations are reported

Exploitation level distribution

Figure 6.18.4.1. Blue and red shrimp in GSAs 9, 10 and 11. Yield per Recruit model (up) and histogram of probability/density for F0.1, Fcurr and level of exploitation values (iter=500)

### 6.18.5 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the a4a stock assessment. The choice of parameter values used followed the procedure described in Section 4.3. An average of the last three years has been used for biological parameters. F status quo was set equal to the last year Fbar value (1.45)
Recruitment shows a fluctuating pattern over the period of the assessment, so it has been estimated from the population results as the geometric mean of the whole time series years (43233 thousands). The assumptions are summarized in Table 6.18.5.1, and the results of the short term forecast are given in Table 6.18.5.2

Table 6.18.5.1 Blue and red shrimp in GSA 9, 10 and 11: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological Parameters |  | mean weights at age, maturation at age, natural mortality at age <br> and selection at age, based average of 2016-2018 |
| Fages 2-5 (2019) $^{\text {and }}$ | 1.45 | F2018 used to give F status quo for 2019 |
| SSB (2019) | 220.7 | Stock assessment 1 January 2019 |
| $R_{\text {age0 }}(2019,2020)$ | 43233 <br> thousands | Geometric mean of the time series years 2006-2018 |
| Total catch (2019) | 277.4 | Assuming F status quo for 2019 |

### 6.18.6 Data Deficiencies

GSA_10 in year 2018 abundance per length classes is reported by 2 mm step while in the Data Call Annex 2 was requested by 1 mm step.

During EWG 1912 landings data from the Mediterranean data call and the FDI data call were compared. As discrepancies were found for ARA in GSA 10 and 11 (more than $50 \%$ for this GSA in the last two years), the stock assessment data for ARA in GSA 9, 10 and 11 was revised with the updated total landings.

### 6.19 GIANT RED SHRIMP IN GSA 9, 10 \& 11

### 6.19.1 Stock Identity and Biology

In the Mediterranean, Aristaeomorpha foliacea (Risso, 1827) is a dominant species of bathyal megafaunal assemblages, and it is sympatric with Aristeus antennatus. Both species have considerable interest for fisheries.
The giant red shrimp is mainly found in the epibathyal and mesobathyal waters of the Mediterranean. Due to a lack of enough information about the structure of giant red shrimp (Aristaeomorpha foliacea) in the western Mediterranean, this stock was assumed to be confined within the GSAs 9,10 and 11 boundaries.
In the GSA 9, A. foliacea is more abundant in the Tyrrhenian Sea, while lower concentrations are present in the Ligurian Sea, where the blue and red shrimp, Aristeus antennatus, is more abundant, and the giant red shimp considerably decreased over time (Masnadi et al., 2018).
In GSA10, this species and the blue and red shrimp are characterised by seasonal variability and annual fluctuations of abundance (Spedicato et al., 1994), as reported for different geographical areas (e.g. Relini, 2007). The giant red shrimp is distributed beyond 350 m depth, but mainly in water deeper than 500 m .
The giant red shrimp shows high densities and well-structured populations with a clear multimodal size pattern in the GSA 11. Seasonal changes have been reported from southern Sardinia in both the vertical distribution and size-related spatial abundance of $A$. foliacea, with large females (preferentially) tending to move gradually deeper (to 650-740 m) from spring to summer (Mura et al., 1997).

Figure 6.18.1.1 Limit of Geographical Sub-Areas (GSAs) 9, 10, 11.

### 6.19.1.1 GROWTH, MATURITY AND NATURAL MORTALITY

Several sets of VBGF parameters have been reported in the DCF database. In GSAs 9 and 10, VBGF curves by sex are available, while in GSA 11 a growth curve for females is provided. Being the VBGF parameters computed in GSA10 a good proxy of the average of the VBGF parameters provided for the three areas, it was decided to use those parameters to slice the size frequency distributions by sex in the three GSAs.
Also for the Length-Weight relationship, several sets of paramentes by sex are provided for GSAs 9 and 10. In GSA11, LW relationship parameters were reported for female only. The average of LW parameters (a and b) was computed and used to estimate mean weight at length and mean weight at age by sex.
The VBGF and LW relationship parameters used are summarized in the following table (Table 6.18.1.1).

Table 6.18.1.1 Giant red shrimp in GSAs 9, 10, 11: VBGF and LW relationship parameters.

|  |  | Units | Females | Males |
| :---: | :---: | :---: | :---: | :---: |
| VBGF <br> parameters | $\mathbf{L}_{\boldsymbol{\infty}}$ | mm | 73.0 | 50 |
|  | $\mathbf{k}$ | years $^{-1}$ | 0.435 | 0.40 |
|  | $\mathbf{t}_{\mathbf{0}}$ | years | -0.10 | -0.10 |
| LW <br> relationship | $\mathbf{a}$ | $\mathrm{mm} / \mathrm{g}$ | 0.004 | 0.003 |
|  | $\mathbf{b}$ | $\mathrm{~mm} / \mathrm{g}$ | 2.52 | 2.65 |

A vector of proportion of mature by age was computed as a weighed average of the vectors available from the DCF database in GSAs 9 and 10. No vector of proportion of mature by age was provided for GSA11.
A natural mortality vector was estimated by sex using the Chen and Watanabe equation and the growth parameters described above. A combined natural mortality vector was then computed as a weighed average of the vectors by sex.
The vector of proportion of mature and the natural mortality vector used in the assessment of giant red shrimp in GSAs 9, 10, 11 are shown in Table 6.18.1.2.

Table 6.18.1.2 Giant red shrimp in GSAs 9, 10, 11: natural mortality and proportion of mature vectors by age.

| Age | Natural <br> mortality | Proportion of <br> matures |
| :---: | :---: | :---: |

| 0 | 1.89 | 0.00 |
| :---: | :---: | :---: |
| 1 | 0.86 | 0.40 |
| 2 | 0.62 | 1.00 |
| 3 | 0.53 | 1.00 |
| $4+$ | 0.48 | 1.00 |

### 6.19.1 DATA

### 6.19.1.1 CATCH (LANDINGS AND dISCARDS)

The annual total landings of giant red shrimp available in the DCF database are reported in Table 6.18.2.1.1 and Figure 6.18.2.1.1. The landings coming from GSA 9 and 11 resulted lower along the time series in comparison with those in GSA 10. Landings data are available in GSA 11 since 2005, while data are available from 2003 in GSAs 9 and 10. In general, landings are showing a fluctuating pattern along the time series, with peaks in 2005 and 2014. In 2017 and 2018, landings show an increase due to a sharp increase in GSA10 (and GSA 11 in 2017). The time series of landings by GSA and gear are shown in Figures 6.18.2.1.2-6.18.2.1.4.

Figure 6.18.2.1.1 Giant red shrimp in GSAs 9, 10, 11: landings by GSA and total landings.

Figure 6.18.2.1.2. Giant red shrimp in GSAs 9, 10, 11: landings trend by gear in GSA 9.

Figure 6.18.2.1.3. Giant red shrimp in GSAs 9, 10, 11: landings trend by gear in GSA 10.

Figure 6.18.2.1.4. Giant red shrimp in GSAs 9, 10, 11: landings trend by gear in GSA 11.

Although the bulk of the production in GSA 10 is coming from the trawl fisheries (mostly deep-water species and mixed demersal and deep-water species trawling), other fisheries (mostly gill nets) provide some contribution to the total production. In GSA 9, the contribution of GNS fisheries is negligible, while in GSA 11 giant red shrimp is exploited by OTB only.

Table 6.18.2.1.1. Giant red shrimp in GSAs 9, 10, 11: landings by GSA and gear.
$\left.\begin{array}{c|c|cc|cc}\hline \text { GSA11 } & \text { GSA 10 } & \begin{array}{c}\text { Other } \\ \text { gears }\end{array} & \text { OTB } & \text { OTB } & \text { OTB }\end{array} \begin{array}{c}\text { Other } \\ \text { gears }\end{array}\right]$

The size structure by year, area and gear is shown in Figures 6.18.2.1.56.18.2.1.7.

Figure 6.18.2.1.5. Giant red shrimp in GSAs 9, 10, 11: LFDs of landings by year and gear of giant red shrimp in GSA 9.

Figure 6.18.2.1.6. Giant red shrimp in GSAs 9, 10, 11: LFDs of landings by year and gear of giant red shrimp in GSA 10.

Figure 6.18.2.1.7. Giant red shrimp in GSAs 9, 10, 11: LFDs of landings by year and gear of giant red shrimp in GSA 11.

Discards of giant red shrimp are negligible. Low values of discards (from OTB) are reported in GSA 9 and 10 only for some years. The discards are summarized in Table 6.18.2.1.2. Despite the low values of discards, LFDs are available, and the data were included into the stock assessment. LFDs of discards of giant red shrimp are shown in Figures 6.18.2.1.8 and 6.18.2.1.9.

### 6.19.1.2 EfFORT

The total effort of the trawl fleets operating in the three GSAs (9, 10, 11), expressed as Days at sea, has shown a progressive decrease in the period 20052018 (Table 6.18.2.2.1 and Figure 6.18.2.2.1). It varied from about 146,000 in 2005 to around 99,000 in 2018, with a minimum in 2012 (94,000). There is no information on the specific effort directed to giant red shrimp.

Table 6.18.2.2.1. Giant red shrimp in GSAs 9, 10, 11: Summary of the OTB effort (Days at sea) by year and GSA (and total for the three GSAs).

| Year | GSA 9 | GSA 10 | GSA 11 | Total |
| :---: | :---: | :---: | :---: | :---: |
| 2005 | 67714 | 50056 | 28645 | 146415 |
| 2006 | 62517 | 38364 | 22836 | 123716 |

### 6.19.1.3 SURVEY DATA

Since 1994, MEDITS trawl surveys have been regularly carried out each year (centred in the early summer). A random stratified sampling by depth (five strata with depth limits at $50,100,200,500$ and 800 m ) is applied. Haul allocation was proportional to the stratum area. All the abundance data (number and total weight of fish per surface unit) are standardized to the $\mathrm{km}^{2}$ using the swept area method.

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance*100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the three GSAs.

Geographical distribution
The following maps show the biomass indices ( $\mathrm{kg} / \mathrm{km}^{2}$ ) by haul of the MEDITS survey. It is evident as the giant red shrimp is more abundant in GSAs 10 and 11 than in GSA 9. Furthermore, the species is mostly present in the southern part of the GSA 9 (Masnadi et al., 2018).

Figure 6.18.2.3.1 Giant red shrimp in GSAs 9, 10, 11: distribution pattern in the period 1994-2018 (MEDITS survey). Maps for the years 1994, 2002, 2010 and 2018 are shown.

Trends in abundance and biomass
The trends of the MEDITS indices (biomass and density) computed on the three GSAs combined are shown in Figure 6.18.2.3.2.
The time series are characterized by wide fluctuations. A first evident peak is observed in 2000, then in 2005 and 2010. Despite a further peak in 2013, the
trend from 2010 onward follows a decreasing pattern. The biomass and density indices obtained from 2014 onwards are among the lowest observed in the whole time series of the MEDITS data in GSAs 9, 10 and 11. In 2018, a sharp increase in biomass and density was observed.

Figure 6.18.2.3.2. Giant red shrimp in GSAs 9, 10 and 11: MEDITS standardized biomass and density indices (10-800 m).

Trends in abundance and biomass by length
The stratified abundance indices by length (by sex and total) computed on the three GSAs combined during the MEDITS surveys from 1994 to 2018 are shown in Figures 6.18.2.3.3-6.18.2.3.5. Also these plots show that the densities observed from 2014 onwards are among the lowest observed in the whole time series of the MEDITS survey in the GSAs 9, 10, 11.

### 6.19.2 Stock ASSESSMENT

FLR libraries were employed in order to carry out a Statistical Catch-at-age (a4a) assessment.

The assessment by means of a4a was carried out using as input data the period 2005-2018 for the catch data and 2005-2018 for the tuning file (MEDITS indices).
A natural mortality vector computed using Chen and Watanabe model was estimated and used in the assessment. Natural mortality vector and proportion of mature are described in section 6.18.1.1. Length-frequency distributions of commercial catches and surveys were split by sex and then transformed in age classes (plus group was set at age 4) using length-to-age slicing with different growth parameters by sex. A correction of 0.5 was applied to $t_{0}$ to align length slicing to assessment year January to December to account for spawning at the middle of the year.

The number of individuals by age was SOP corrected [SOP = Landings / $\Sigma$ (total catch numbers at age a x catch weight-at-age a)]. However, the correction factor that resulted was low.

In both catches and survey, a plus group at age 4 was set. The plus group in the survey was estimated separately and not estimated using the a4a routine.
$F_{b a r}$ range was fixed at 1-3.

The assessment was performed by sex combined. Given that the landings were composed mainly of individuals between 1 and 3 years, these ages were selected as $F_{b a r}$ range.

The model settings that minimized the residuals and showed the best diagnostics outputs were used for the final assessment, and are the following:

Fishing mortality sub-model: fmodel $=$ factor(replace(age, age>3,3))+s(year, $\mathrm{k}=9$ )
Catchability sub-model: qmodel $=\operatorname{list}(\sim$ factor(age) $)$
SR sub-model: srmod = geomean (CV=0.2)
Model <- sca(stock = stk, indices = idx, fmodel, qmodel, srmod)
The n1model and vmodel used in the final fit are the default ones:
n1model <- ~s(age, $k=3$ )
vmodel <- list( $\sim s(a g e, k=3), \sim 1)$

Figure 6.18.3.3. Giant red shrimp in GSAs 9, 10 and 11: fishing mortality by age and year obtained from the a4a model (2005-2018).

Figure 6.18.3.4. Giant red shrimp in GSAs 9, 10 and 11: catchability of the survey by age and year obtained from the a4a model.

The log residuals for both the catches and the survey do not show any particular trend or issue.indices show positive residuals at age 2 and negative residuals at age 3 (Figures 6.18.3.5 and 6.18.3.6). The fitting of the survey shows some problems (Figures 6.18.3.9), probably due to the poor internal consistency of the survey. Despite this, the diagnostics are considered acceptable and the a4a model is acceptable as a basis for advice.
log residuals of catch and abundance indices by age

Figure 6.18.3.10. Giant red shrimp in GSAs 9, 10 and 11: internal consistency of the catch-at-age data.

Figure 6.18.3.11. Giant red shrimp in GSAs 9, 10 and 11: internal consistency of the catch-at-age data of the MEDITS survey.

The effect of cryptic biomass was investigated, and did not show any relevant issue, as the biomass of the plus group (age 4+) is always around $5 \%$ of the total SSB.

The retrospective analysis shows that the assessment model is moderately stable, and the catch estimates obtained by the a4a assessment are fitting well the observed catches. There is some evidence of retrospective bias, overestimation of SSB and underestimation of F , probably linked to large negative and then possitive residuals in survey data in last 4 years. The instability does not affect the conclusion $F>F_{\text {MSY }}$ with $\mathrm{F}_{\text {MSY }}=0.45$ (Section 6.19.4)

| 2018 | 264215 | 318090 | 210340 | 435.9 | 539.5 | 332.3 | 681.8 | 1.37 | 1.71 | 1.02 |

### 6.19.3 Reference Points

The STECF EWG 19-10 recommended to use $\mathrm{F}_{0.1}$ as proxy of $\mathrm{F}_{\text {MSy. }}$. The library FLBRP available in FLR was used to estimate $\mathrm{F}_{0.1}$ from the stock object resulting from the outputs of the a4a assessment.

Current $F$ (1.37), estimated as the $F_{\text {bar1-3 }}$ in the last year of the time series, 2018) is higher than $\mathrm{F}_{0.1}(0.45)$, chosen as proxy of $\mathrm{F}_{\mathrm{mSy}}$ and as the exploitation reference point consistent with high long-term yields, which indicates that giant red shrimp stock in GSAs 9, 10, 11 is over-exploited.

### 6.19.4 Short term Forecast and Catch Options

A deterministic short term prediction for the period 2019 to 2021 was performed using the FLR libraries and scripts, and based on the results of the a4a stock assessment.

The input parameters for the deterministic short-term predictions were the same used for the a4a stock assessment and its results. An average of the last three years has been used for weight at age, maturity at age, while the Far terminal (2018) from the a4a assessment was used.

Recruitment (age 0) has been estimated from the population results as the geometric mean of the whole time series (252911.7 thousand individuals).

Table 6.18.5.1 Giant red shrimp in GSAs 9, 10, 11: Assumptions made for the interim year and in the forecast.

| Variable | Value | Notes |
| :--- | :---: | :--- |
| Biological Parameters |  | mean weights at age, maturation at age, natural mortality at age <br> and selection at age, based average of 2016-2018 |
| Fages 1-3 (2019) | 1.37 | F current in the last year |
| SSB (2019; middle of <br> the year) | 343.6 t | Stock assessment 1 January 2019 |
| $\mathrm{R}_{0}(2019,2020,2021)$ | 252911.7 <br> thousands | Geometric mean of the whole time series (2005-2018) |
| Total catch (2019) | 467.7 t | Assuming F status quo for 2019 |

Table 6.18.5.1 Giant red shrimp in GSAs 9, 10, 11 : short term forecast in different $F$ scenarios. The SSB estimates are computed at the middle of the year.

| Rationale | Ffactor | Fbar | $\begin{aligned} & \text { Catch } \\ & 2018 \end{aligned}$ | $\begin{aligned} & \text { Catch } \\ & 2019 \end{aligned}$ | $\begin{aligned} & \text { Catch } \\ & 2020 \end{aligned}$ | $\begin{aligned} & \text { Catch } \\ & 2021 \end{aligned}$ | $\begin{gathered} \text { SSB } \\ 2020 \end{gathered}$ | $\begin{gathered} \text { SSB } \\ 2021 \end{gathered}$ | $\begin{gathered} \text { Change } \\ \text { SSB } \\ 2019- \\ 2021 \text { (\%) } \\ \hline \end{gathered}$ | $\begin{gathered} \text { Change } \\ \text { Catch } \\ 2018- \\ 2020(\%) \\ \hline \end{gathered}$ |

### 6.19.5 Data Deficiencies

At STECF 18-12, no sex ratio (and maturity vector) at length was available for GSA 11, thus the vectors available for GSA 10 were used to split the LFDs of GSA 11 in LFDs by sex. This information was made available to STECF 19-10, then used to prepare the stock object.
In terms of coverage, information on landings for quarter III in 2017 and quarter I in 2018 for GSA 10 was missing. The information was requested to the Italian National Correspondent and made available to the EWG in due time.

In GSA 11, landings data for OTB_DWS were missing from 2015 to 2018. Landings data were recovered from the FDI data. This required the assessment to be re-run after the EWG.

As concerns MEDITS survey data, missing values in "pfrac" and "pechan" (TC) of hauls 29 and 67 of GSA10 in 2017 were pointed out. The correct values were recovered from TB: 2877 g and 2342 g in haul 29 and 67, respectively.
The impact on the assessment was then low.

ToR 8. To summarize and concisely describe all data quality deficiencies, including possible limitations with the surveys of relevance for stock assessments and fisheries. Such review and description are to be based on the data format of the official DCF data call for the Mediterranean Sea launched on May 2019. Identify further research studies and data collection which would be required for improved fish stock assessments.

ToR 9. To ensure that all unresolved data transmission issues encountered prior to and during the EWG meeting are reported on line via the Data Transmission Monitoring Tool (DTMT) available at https://datacollection.jrc.ec.europa.eu/web/dcf/dtmt. Guidance on precisely what should be inserted in the DTMT, log-on credentials and access rights will be provided separately by the STECF Secretariat focal point for the EWG.

### 7.1 EUROPEAN HAKE IN GSA 1, 5, 6 \& 7

The same data deficiencies encountered in EWG 18-12 were found in last year (2018) data and within the whole time series.

France data
In some years and for some hauls, hake MEDITS data seem biased due to have applied a very high raising factor. This fact could reflects itself in TB data too.

Spain data
In some years and for some hauls, hake MEDITS data seem biased due to have applied a very high raising factor. This fact could reflects itself in TB data too.

### 7.2 DeEP-WATER ROSE SHRIMP IN GSA 1, 5, 6 \& 7

Data from DCF 2018 as submitted through the Official data call in 2019 were used.
In GSA 1, no length frequency distributions of landing were available for 2002 and for all years of OTB-MDDWSP.

In GSA 5, no length frequency distributions of landing were available for 2016 and for 2009 of OTBMDDWSP.

In GSA 6, no length frequency distributions were available for all years of OTB-MDDWSP. The length frequency distribution in 2015 had an extremely high number of individuals in the length class 33.

In GSA 7, only the length frequency distributions of landing for Spanish OTB were available. They cover the period 2009-2018. No length frequency distributions of landing were available for OTBMDDWSP.

Length and age frequency distributions of the discards were not available in the DCF data.
Issues with the MEDITS data in GSA 1 were pointed out. The TC in 2013 contains two hauls (16 and 38) with wrong values in "pfrac". The correct values ( 854 and 261 g , respectively) were recovered from "pechan". The number of individuals were also corrected in TB, gathering them from TC.

In the MEDITS data of GSAs 1,6 and 7 there are animals of lengths higher than 50 mm carapax length, which were considered wrong.

The MEDITS length frequency distributions in GSA 5 for 2001 should be checked thoroughly because are considered to be wrong.

### 7.3 RED MULLET IN GSA 1

EWG 19-10 decided not to include year 2003 in the assessment input due to some inconsistencies reported in the length frequency distribution of landings. Scientists from the corresponding country (Spain) agreed that being the first year of sampling for the DCF, the reported values are incomplete or misreported. Discards data were also incomplete and misreported for several years. Gaps appeared throughout the years 2003-2007 and 2010. Length frequency distribution for the discards reported only for 2017 and 2018. Inconsistencies were also apparent in the MEDITS Survey Index for the year 2006 and the year 2011 was missing. Standardized length frequency distribution was recalculated for this year.

According to ToR 9, the EWG19-10 reported on line via the Data Transmission Monitoring Tool (DTMT) available at https://datacollection.jrc.ec.europa.eu/web/dcf/dtmt.

The EWG18-12 also summarized and concisely described catch and effort data deficiencies, in terms of coverage and quality.

### 7.4 RED MULLET IN GSA 6

A change in the coding of the métiers was observed in 2010 and 2018.
MEDITS length frequencies distributions should be checked for sizes 50 to 100 (probably change of unit).

### 7.5 Red mullet in GSA 7

The analysis of MEDITS data, showed a problem in the size distribution of Nep in 2013 with two anomalous peak. A deeper check of row data showed wrong nbtot reported number (350) for the haul coded 150

### 7.6 Norway LOBSTER IN GSA 6

A lack of growth parameters and length weight relationship coefficient has been detected. As previously observed, the length distribution in 2001 is very different from all the other years and reported for greater bins than usual.

### 7.7 European hake in GSA 9, 10 and 11

GSA10: unlikely length measures (total length more than 100 cm ) were found for European hake (HKE) in MEDITS data in 2017. Regarding commercial data, LFDs and relative landings are missing for 2017 third quarter and 2018 first one. LFDs in 2018 are reported with a 2 cm step. No discard data are available for 2018. Very low discard values in 2017, compared to the previous year's time series.

MEDITS data provided for hake in GSA11 present some issues in the TC file, maybe due to incorrect raising procedures. In 2006, for example, haul 71 presents a raising factor of 885 only for size 395 ; in 2008, haul 30 presents a raising factor of 391 for lengths $280,300,310$ and 420 . This results in biased LFD patterns.

### 7.8 Deep-water rose shrimp in GSA 9, 10 and 11

Data from DCR-DCF database as submitted through the Official data call in 2019 were used for the stock assessment.

Landing data. The time series of landing data in biomass available in the database were different among the three GSAs: 2003-2018 for GSA09, 2002-2018 for GSA10 and 2009-2018 for GSA11.

The length frequency distributions of the landing for GSA09 are available for the period 2003-2018 (year 2002 is missing). For GSA10, data are not available for 2003. The historical data series for GSA11 includes the period 2009-2018 (the years 2002-2008 are missing). In GSA10, length frequency distributions and relative landings are missing for the third quarter of 2017 and for the first quarter of 2018. Although the assessment started from 2009, the lack of data in the previous years in GSA11 has a low impact as the landing in this area are very low if compared to those observed in GSA9 and GSA10. Concerning the lack of quarters in GSA10 in the last two years, a sop correction was necessary.

Discard data. The biomass discarded and the related length frequency distributions of Deep-water rose shrimp in GSA09 are available for the period 2009-2018. In GSA10, the data on discard are available for 2006 and for the years 2009-2017. The lack of data in 2018 for GSA10 had a low impact on the assessment as, on average, discard in GSA10 represents about $2 \%$ of the total catch. With regard to GSA11, there are no data on this fraction of the catch. Due to the low catches of DPS in GSA11 the discard of this species could be considered negligible in the area. It should be emphasized that the Italian national data collection program did not provide for the collection of discard before 2006 and in the years 2007-2008.

### 7.9 RED MULLET IN GSA 9

The EWG19-10 did not find any particular data deficiency for this stock, in terms of data quality.

### 7.10 Red mullet in GSA 10

EWG19-10 has noted that landing and discard data of the 3rd quarter of 2017 were missing for all gears and fisheries, as well as the landing and discard of the first quarter 2018. The missing landing data were requested to the Member State and received in the due time to carry out the assessment. Being available the landing data of the third quarter in 2017, the discard of the third quarter was estimated.

Despite these deficiencies, addressed on time for the analyses, an uncommon length structure (between 15 and 20 cm ) associated to the discard of the GTR with vessel length VL0006 in 2018 was noticed in quarter 4 . Even the ratio between discard and landing for this stratum seems considerably high (D/L around $400 \%$ ) for the type of fishery. This anomaly seems due to the only 4 individuals sampled in the discard in only 1 sample collected in the stratum.

The EWG19-10 reported on line via the Data Transmission Monitoring Tool (DTMT) available at https://datacollection.jrc.ec.europa.eu/web/dcf/dtmt.

### 7.11 Norway LObster in GSA 9

Landings in 2017 were considered unreliable, as very high. Despite official data were not revised, the experts informed that a new estimation of landings was produced, and was provided to STECF 19-10.
The impact on the assessment was then low.

### 7.12 NORWAY LOBSTER IN GSA 11

Growth parameters previous to 2015 were available only for males, as well as length weight relationship coefficients. However, growth parameters for both sexes have been submitted since 2016.

### 7.13 BLUE AND RED SHRIMP IN GSA 1

There were issues with the dataset regarding the survey index for 2009 that were identified before the meeting. These issues (reporting of a very large individual with $\mathrm{CL}=362 \mathrm{~mm}$ and duplicate records for some length classes) were resolved before the index was prepared for running the assessment.

### 7.14 BLUE AND RED SHRIMP IN GSA 6 AND 7

Considering that blue and red shrimp shows sex dimorphism, females grow more than males, the lack of growth information on both sexes, instead of combined parameters, could potentially bias the slicing procedure.
The assessment of blue and red shrimp in GSAs 6 \& 7 showed some discrepancies related to the method of slicing LFD data. The STECF EWG suggest that in future the possible methods of slicing LFD data (of fishes and invertebrates), as well as growth information they are using, are thoroughly reviewed, checked and tested, taking into consideration the seasonality of growth, reproduction and moulting processes, in order to define and ably the best practice in cohort slicing for stock assessment.

### 7.15 BLUE AND RED SHRIMP IN GSA 9, 10 AND 11

GSA_10 in year 2018 abundance per length classes is reported by 2 mm step while in the Data Call Annex 2 was requested by 1 mm step.

### 7.16 GIANT RED SHRIMP IN GSA 9, 10 AND 11

At STECF 18-12, no sex ratio (and maturity vector) at length was available for GSA 11, thus the vectors available for GSA 10 were used to split the LFDs of GSA 11 in LFDs by sex. This information was made available to STECF 19-10, then used to prepare the stock object.

In terms of coverage, information on landings for quarter III in 2017 and quarter I in 2018 for GSA 10 was missing. The information was requested to the Italian National Correspondent and made available to the EWG in due time.
In GSA 11, landings data for OTB_DWS were missing from 2015 to 2018. Landings data were recovered from the FDI data. This required the assessment to be re-run after the EWG.
As concerns MEDITS survey data, missing values in "pfrac" and "pechan" (TC) of hauls 29 and 67 of GSA10 in 2017 were pointed out. The correct values were recovered from TB: 2877 g and 2342 g in haul 29 and 67, respectively.
The impact on the assessment was then low.

## STECF 2018 Report of EWG 18-12

## 9 CONTACT DETAILS OF EWG-19-10 PARTICIPANTS

1 - Information on EWG participant's affiliations is displayed for information only. In any case, Members of the STECF, invited experts, and JRC experts shall act independently. In the context of the STECF work, the committee members and other experts do not represent the institutions/bodies they are affiliated to in their daily jobs. STECF members and experts also declare at each meeting of the STECF and of its Expert Working Groups any specific interest which might be considered prejudicial to their independence in relation to specific items on the agenda. These declarations are displayed on the public meeting's website if experts explicitly authorized the JRC to do so in accordance with EU legislation on the protection of personnel data. ## GETTING IN TOUCH WITH THE EU

## In person

All over the European Union there are hundreds of Europe Direct information centres. You can find the address of the centre nearest you at: https://europa.eu/european-union/contact en

On the phone or by email
Europe Direct is a service that answers your questions about the European Union. You can contact this service:

- by freephone: 0080067891011 (certain operators may charge for these calls),
- at the following standard number: +32 22999696, or
- by electronic mail via: https://europa.eu/european-union/contact en

## FINDING INFORMATION ABOUT THE EU

Online
Information about the European Union in all the official languages of the EU is available on the Europa website at: https://europa.eu/european-union/index_en

## EU publications

You can download or order free and priced EU publications from EU Bookshop at: https://publications.europa.eu/en/publications.
Multiple copies of free publications may be obtained by contacting Europe Direct or your local information centre (see https://europa.eu/european-union/contact en).

## STECF

The Scientific, Technical and Economic Committee for Fisheries (STECF) has been established by the European Commission. The STECF is being consulted at regular intervals on matters pertaining to the conservation and management of living aquatic resources, including biological, economic, environmental, social and technical considerations.

## The European Commission's science and knowledge service Joint Research Centre

## JRC Mission

As the science and knowledge service of the European Commission, the Joint Research Centre's mission is to support EU policies with independent evidence throughout the whole policy cycle.
