# A revised catalogue of $\boldsymbol{\delta}$ Sct stars ${ }^{\star}$ 

E. Rodríguez, M.J. López-González, and P. López de Coca<br>Instituto de Astrofísica de Andalucía, CSIC, P.O. Box 3004, E-18080 Granada, Spain

Received February 25; accepted April 5, 2000

#### Abstract

An extensive and up-dated list of $\delta$ Sct stars is presented here. More than 500 papers, published during the last few years, have been revised and 341 new variables have been added to our last list, six years ago. This catalogue is intended to be a comprehensive review on the observational characteristics of all the $\delta$ Sct stars known until now, including stars contained in earlier catalogues together with other new discovered variables, covering information published until January 2000. In summary, 636 variables, 1149 references and 182 individual notes are presented in this new list.

Key words: stars: variables: $\delta$ Sct — stars: oscillations stars: fundamental parameters - techniques: photometric

## 1. Introduction

$\delta$ Sct stars are regularly pulsating variables located in the lower part of the Cepheids instability strip showing short periods $(<0 \mathrm{~d} 3)$ and visual amplitudes ranging from a few thousandths of a magnitude to several tenths, with typical amplitude of about $0^{\mathrm{m}} 02$. The majority of these stars belong to Population I, however a few variables show low metallicities and high spatial motions typical of Population II. This second small group may be astrophysically different from the normal Population I $\delta$ Sct variables. They are called SX Phe stars and very few are known in the field. Recently, a large number of these variables are being discovered in globular clusters. A number of reviews on $\delta$ Sct variables are available in the literature, e.g. Breger (1979, 1995, 1999, 2000), Eggen (1979), Wolff (1983), Tsvetkov (1990), López de Coca et al. (1990),

[^0]Kurtz (1994, 1996), Rodríguez et al. (1994; hereafter R94), García et al. (1995), Garrido (2000), Jiang et al. (2000).

During the last few years the number of new variables is enormously increasing. Additionally to the immense effort developed by individual groups, a number of long-term monitoring projects are being carried out leading to the discovery of a lot of new variables including $\delta$ Sct pulsating stars. Several of these projects are still in progress as, e.g., EROS (Aubourg et al. 1995), DUO (Alard 1996), PLANET (Albrow 2000), etc., and their results will be available in the next future. In other cases, MACHO (Alcock et al. 2000) and OGLE (Udalski et al. 1994, 1995a,b, 1996, 1997) projects, a large number of $\delta$ Sct stars have been discovered already and probably more new variables will be still found. Contributions from OGLE side-projects are being also very important, especially for SX Phe-type variables in globular clusters. Furthermore, a lot of $\delta$ Sct variables have been detected by the Hipparcos mission (ESA 1997) and more new members are expected from the Tycho mission (Annex B; ESA 1997).

Additionally to new variables, new catalogues on different parameters have been recently published. This information has been used to up-date each variable in our list, using the most recent catalogues available in the bibliography on photometry (Strömgren and Johnson systems), spectral types, rotational and radial velocities, multiplicity and parallaxes.

The aim of this work is to present an extensive and up-dated list of $\delta$ Sct stars. This catalogue is intended to be a comprehensive review on the observational characteristics of all known $\delta$ Sct stars, including stars contained in earlier catalogues together with other new discovered variables, covering information published until January 2000. Field SX Phe stars have been also included in our list. A catalogue on SX Phe variables in globular clusters will be the subject of another work (Rodríguez \& López-González in preparation).

## 2. The catalogue

### 2.1. Description

The stars and their most significant parameters are listed in Table 1 together with references to studies of individual stars and notes for a number of variables. Table 2 lists our identification for the $\delta$ Sct variables observed by MACHO project. In the present paper only the first page of Table 1 is printed as an example. The full Table 1 together with Table 2 are accessible in electronic form and can also be requested from the authors. In summary, the new catalogue contains 636 variables, 1149 references and 182 individual notes. Each star in the list has been carefully examined before being included in Table 1. Several tens of stars were rejected mainly because either time scales of variation or signal/noise ratio of their light curves do not allow us to definitively classify them as $\delta$ Sct variables and they are not listed in the table. In fact, most of them have been previously considered only as suspected $\delta$ Sct variables by earlier authors.

The list is given according to their 2000.0 equinox equatorial coordinates ordered by increasing right ascension. Several catalogue identifications appear for each star according to the source: HD (Henry Draper Catalogue), HR (Bright Star Catalogue), SAO (Smithsonian Astrophysical Observatory Star Catalogue), BD (Bonner Durchmusterung), CD (Cordoba Durchmusterung), CPD (Cape Photographic Durchmusterung), HIP (Hipparcos Catalogue), CCDM (Catalogue of the Components of Double and Multiple Stars) and GCVS (General Catalogue of Variable Stars). In some cases, when it is known, another designation has been also used (Other). Similarly to the R94 catalogue, periods correspond to the dominant pulsation mode in every case while amplitudes correspond to the mean full visual amplitude of the light curve. The main sources of information have been the Name Lists of Variable Stars Nos. 72, 73 (Kazarovets \& Samus 1995, 1997) and 74 (Kazarovets et al. 1999). In addition, the Hipparcos catalogue (ESA, 1997) has been also taken into account, together with all the available bibliography in the last few years.

In this new catalogue, more than $50 \%$ of the variables are new in relation to our last list (R94 catalogue). The list of R94 contained 298 variables, three of them have been eliminated (UW CVn, V879 Aql and UX Mon). UW CVn and V879 Aql seem to be W UMa-type binary systems with periods of 0.292 and 0 d 271 , respectively (Kopacki \& Pigulski 1995, 1998). In the case of UX Mon, it was thought to be an Algol-type binary system ( $P=5.9$ ) where the primary component is a $\delta$ Sct pulsating star with a period of about 1 hour. However, later observations by Olson \& Etzel (1995) do not confirm the $\delta$ Sct-like variations. These authors found variability with a time scale of several hours ( $>8$ hours) as due to mass transfer in
this active binary. Another possibility might be $\gamma$ Dor-like variations in the primary component.

Hence, 295 variables were already listed in the R94 catalogue and 341 are new. Nearly all of these new variables (337) have been discovered through the years 1994 to 2000 . The main contributions come from the Hipparcos mission (88 new variables; ESA 1997, Kazarovets et al. 1999) and the OGLE (54; Udalski et al. 1994, 1995a,b, $1996,1997)$ and MACHO (84; Alcock et al. 2000) projects. In the case of OGLE project, 56 variables of this type have been observed but only 54 are new. The variables BWCV82 and BW1-V23 were already known as V4117 Sgr and V1363 Sgr, respectively (Blanco 1984). In the case of MACHO project, $90 \delta$ Sct variables are listed but only 84 are new. The variables MACHO-58 and MACHO59 are V1363 Sgr and V4117 Sgr, respectively. In addition, the variables MACHO-56, MACHO-57, MACHO-62 and MACHO-63 were previously identified by the OGLE project as BW10-V141, BW1-V109, BW7-V79 and BW3V93. Thus, even avoiding the contributions from these three main projects, a large number (111) of new variables have been discovered since 1994. These mean the $17 \%$ of the total sample of $\delta$ Sct pulsating stars known up to date. The last variable included in our catalogue is HD 81882, discovered by Rodríguez \& Rolland (2000) during the night of January 29, 2000. On the other hand, more than 500 papers, published during the last few years, have been revised and 282 new references have been added to the corresponding list.

The main source of information for Strömgren photometry has been the catalogue of Hauck \& Mermilliod (1998). In the case of Johnson photometry, the catalogues of Mermilliod et al. (1997) and Hipparcos (ESA 1997) have been mainly used. Sometimes, individual valuable papers have been used to determine the Strömgren indices, especially for variables with large amplitudes. In a few cases, the visual $V$ magnitudes come from Simbad Database (1999). The main source for Spectral Types have been the Michigan (Houk \& Cowley 1975 (Vol. 1); Houk 1978 (Vol. 2); Houk 1982 (Vol. 3); Houk \& Smith-Moore 1988 (Vol. 4)) and Hipparcos (ESA 1997) catalogues. In addition, the lists of Gray (1988), Gray \& Garrison (1989), Gray \& Corbally (1993), Abt \& Morrell (1995) and Simbad Database (1999) have been also used.

In the case of rotational velocities ( $v \sin i$ ), the catalogue of Uesugi \& Fukuda (1982) has been the most used. In addition, the lists of McNamara (1985), Abt \& Morrell (1995), Solano \& Fernley (1997) and Medeiros \& Mayor (1999) have been also taken into account. The main sources for radial velocities have been the lists of Duflot et al. (1995), Fehrenbach et al. (1997) and Grenier et al. (1999a,b). Finally, in all cases, the parallaxes come from the Hipparcos catalogue (ESA 1997).

These sources have been used to up-date the data catalogued in the new list, including values already available in the R94 catalogue. However, in the majority of the

Fig. 1. Distribution of the variables in the catalogue $(N)$ as function of the spectral type ( $S T$ )
cases, the old values do not change. The main sources for changes have been $V$ and $B-V$ from the Hipparcos catalogue (ESA, 1997) and rotational velocities from Solano \& Fernley (1997), but no trends are shown with the new values.

### 2.2. Content

Figures 1 to 6 give us some insight about the content of the catalogue. Figures 1 to 4 show the corresponding distributions as functions of the spectral type, rotational velocity, visual amplitude and period, respectively. Figures 5 and 6 display some interesting cross-correlations found between these parameters. In Fig. 1, only variables with well defined available spectral types have been taken into account, hence peculiar stars were not included in the sample. As it can be seen, the majority of these stars have spectral types between A6 to F2, with a peak at F0.

In relation to Fig. 2, by comparing this figure with Fig. 7 of the R94 catalogue, the peak corresponding to the interval $60-80 \mathrm{~km} \mathrm{~s}^{-1}$ has disappeared. Now, the distribution is more smoothed and the stars seem to be uniformly distributed in all the range for rotational velocities lesser than $180 \mathrm{~km} \mathrm{~s}^{-1}$. Only a peak remains for very low values of $v \sin i$. This peak is due to the variables with high amplitudes of luminosity variation. This is confirmed when we plot Fig. 5, where the visual amplitudes versus rotational velocities are shown. Similarly to R94, these two figures point out that stars with large rotational velocities do not exhibit large amplitudes, that is, the variables displaying large amplitudes are very slow rotators. In fact, the mean value of $v \sin i$ for $\delta$ Sct variables with $\Delta V \leq 0{ }^{\mathrm{m}} 03$ is found to be of $109( \pm 58) \mathrm{km} \mathrm{s}^{-1}$ whereas this is much smaller for the large amplitude pulsators $(<v \sin i>=22( \pm 10)$ $\mathrm{km} \mathrm{s}^{-1}$ for the variables with $\Delta V \geq 0^{\mathrm{m}} 1$ and a very similar value is found for the variables with $\Delta V \geq 0{ }^{\mathrm{m}} 3$ ).

Fig. 5. Full average of the visual amplitude $(\Delta V)$ versus rotational velocity $(v \sin i)$

This agrees well when considering the parametric resonance as a mechanism to limit the amplitude of the pulsations, as mentioned in R94.

In relation to Fig. 3, the distribution is similar to that found from the R94 sample. These stars show visual amplitudes from a few thousandths of a magnitude to several tenths. The majority of them present small amplitudes (a few hundredths) with a typical value of about $0 .{ }^{\mathrm{m}} 02$. Moreover, the number of low amplitude variables increases nearly exponentially as decreasing the amplitude. In particular, nearly $30 \%$ of them show amplitudes smaller than 0 m. 02. It suggests we cannot exclude the possibility that many of the apparently nonvarying stars in the $\delta$ Sct region vary but with undetectable amplitudes. On the other hand, the distribution shown in our Fig. 4 resembles the corresponding one found from the R94 list. Similarly to the earlier catalogue, Fig. 4 point out that the majority of these variables show short periods (about $80 \%$ of them have periods shorter than 0.15 ) and the number of variables decreases as the period is increasing. It can be due to stars with longer periods are more evolved, hence the probability of finding one star in this region of the $H-R$ diagram is smaller. Other reasons can be the selection effects mentioned in the R94 catalogue.

Additionally to the correlation found between the visual amplitudes and rotational velocities, another interesting result is displayed in Fig. 6 where the mean periods are shown versus the spectral type. As it can be seen, the periods of the variables tend to increase when the spectral types are later. It can be explained as an evolutionary effect due to the hotter $\delta$ Sct stars tend to be near the main sequence while the variables presenting the latest spectral types are more evolved (spectral class II and III). However, no correlations are found for $v \sin i$ versus spectral type or $v \sin i$ versus period. From an observational point of view, it seems to be that stars in main sequence

Fig. 6. Mean period $(P)$ versus spectral type $(S T)$
rotate faster than evolved stars, however no correlation is found between $v \sin i$ and spectral types for the $\delta$ Sct-type variables. It might be due to a selection effect because there are few $\delta$ Sct stars with long periods and available $v \sin i$ values. It might also be that other parameters have to be taken into account.
Acknowledgements. This catalogue is dedicated to the memory of our great friend and observer in the field of $\delta$ Sct stars Salvador F. González-Bedolla deceased November 1, 1996. The authors are in debt to many people who have contributed to improve this catalogue. Some of them are Dr. Balona, Beaulieu, Breger, Frandsen, Hintz, Jiang, Liu, Mantegazza, Minniti, Paunzen, Piquard, Sasselov, Udalski. Especial acknowledgements are made to Dr. Handler, Kaluzny, Kim, Koen, Templeton and Zhou. Acknowledgements are also especially made to M.C. Romero for making available many papers used in this investigation and V. Costa for proofreading. This research was supported by the Junta de Andalucía and the Dirección General de Enseñanza Superior e Investigación Científica (DGESIC) under project PB98-0499. This work has made use of the Simbad database, operated at CDS, Strasbourg, France.
