Polymorphic microsatellite loci for the cardinal fish (*Apogon imberbis*)

Abstract Eight polymorphic microsatellite loci were isolated and characterized for the Cardinal fish (*Apogon imberbis*), a coastal-reef fish endemic to the Mediterranean Sea. Characterization of 30 Cardinal fish individuals from the western Mediterranean showed moderate to high allelic diversity ranging from 6 to 19 alleles per locus. Two loci showed significant departures from Hardy-Weinberg equilibrium presumably due to null alleles. No evidence of linkage disequilibrium was found for any locus pairwise comparisons. This microsatellite set could be useful for any basic population genetic studies of this species.

Keywords Microsatellite · *Apogon imberbis* · Cardinal fish · Apogonidae

Cardinal fishes are coastal-reef marine fish of the genus *Apogon*. This genus comprises a large number of species (174) distributed from the tropical Indo-West

Pacific to the Atlantic Ocean and the Mediterranean Sea (Kuitert and Kozawa 1999). However, only one species, *Apogon imberbis*, exists within the Mediterranean Sea (Tortonese 1986). All species appear to have a peculiar reproductive strategy in which internal fertilization is achieved by transferring the sperm into the oviduct of the female through the male's ventral fins (Thresher 1984). The fertilized eggs are then released by the female and picked up by the male who broods them in his mouth until hatching. This form of male parental care has probably been responsible for the considerable interest in the genus, resulting in studies of mating behavior (Kuwanura 1983), filial cannibalism (Smith 1992), gamete biology (Lahnsteiner 2003), parental care effort (Okuda 2001) and molecular phylogeny (Mabuchi et al. 2006). Little attention, however, has been paid to the Mediterranean species for which only one study covering basic aspects of its reproductive behavior and growth rate pattern is available (Garnaud 1962). Furthermore, nuclear genetic information is scarce with just a single study reporting variability at nuclear loci for a single species of the genus (Miller-Sims et al. 2004). Here, we report the characterization of eight microsatellite loci developed in *A. imberbis* with the aim of evaluate dispersal strategies in this marine mouth-brooding fish.

Microsatellite markers were identified through the development of an enriched genomic library as described in Glenn et al (2000). DNA was extracted from 10 individuals from the Western Mediterranean by the phenol-chloroform method (Sambrook et al. 1989). Simultaneous restriction-ligation of genomic DNA was carried out using *RsaI* restriction enzyme and double stranded linker-adapted primers according to Hamilton et al (1999). Ligated DNA was size selected

GenBank Accession No., Locus name, repeat motif, fluorescent dye-primer sequence, number of alleles, Allele size range, H_O: observed heterozygosity, H_E: expected heterozygosity under Hardy-Weinberg equilibrium, F_{IS}: inbreeding coefficient, *P < 0.05

and enriched by magnetic bead selection with a biotin-labeled probe mixture consisting of (GT)₁₀ and (CT)₁₀ at 10 μ M each. Enriched DNA was eluted in 200 μ l dH₂O from the bead probes and concentrated by vacuum centrifugation to a final concentration of ~100 ng/ μ l. Recovered DNA was then purified and cloned using pGEM-T Easy Vector II (Promega). A total of 56 positive clones were screened and checked for inserts using ABI PRISM BigDye Terminator Cycle kit (Applied Biosystems) and resolved on an ABI 3100 Genetic Analyser (Applied Biosystems). Primer pairs for eight potential usable microsatellite loci were designed using OLIGO 6.4 software. Polymorphism was tested by multiplex PCR reactions performed in 25 μ l total volume, which include 50 ng of DNA, 2 mM of MgCl₂, 0.75 μ M of each primer, 200 μ M dNTP's, 1X reaction buffer [75 mM Tris-HCl, 20 mM (NH₄)₂SO₄] and 0.5 units Taq polymerase (BIOTAQ). Reaction conditions were as follows: an initial denaturation step of 5 min at 95°C, eight cycles consisting of 30 s at 92°C, 30 s at 53.5°C annealing temperature, 30 s at 72°C followed by an additional twenty eight cycles at 55.5°C annealing temperature. Microsatellite variability was assessed in 30 individuals from the western Mediterranean. Individuals were genotyped by assessing allele size on an ABI 3100 Genetic Analyser (Applied Biosystems) using forward primers labelled with FAM (Sigma) and NED, PET and VIC (Applied Biosystems). Allele scoring was carried out using GENEMAPPER version 3.5 software (Applied Biosystems). Expected and observed values for heterozygosity were

determined using ARLEQUIN V.2.0 (Schneider et al. 2000). The number of alleles per locus, allele size range as well as deviations from Hardy-Weinberg expectations and linkage disequilibrium between pairs of loci were estimated using FSTAT V.2.9 (Goudet 1995). All loci were polymorphic, the total number of alleles per locus and heterozygosities estimates are listed in Table 1. We found no evidence of linkage disequilibrium between locus pairs. Two loci showed significant departures from Hardy-Weinberg equilibrium (Aimb22, Aimb29). This could be due to the presence of null alleles or the inclusion of individuals from different populations in the analysis.
